A multi-institutional noninferiority trial from the NCIC randomized 936 predominantly low-risk men to 66 Gy in 2-Gy fractions over 6.5 weeks versus 52.5 Gy in 2.625 Gy over 4 weeks (Lukka et al., 2005). The median follow-up was 5.7 years. The 5-year risk for biochemical or clinical failure was 53% in the standard fractionation arm and 60% in the hypofractionation arm (difference −7%, 90% CI, −12.6% to −1.4%). Although acute toxicity was slightly higher with hypofractionation (11.4 % vs. 7%, difference −4.4%; 90% CI, −8.1% to −0.6%), late toxicity was low for both arms (3.2%). The major weakness of this trial was the low dose used for both arms that resulted in high failure rates. It was designed before development of the alpha/beta ratio hypothesis, and the hypofractionated dose was biologically less effective than the standard arm using an alpha/beta ratio of 1.5.

Yeoh et al. (2011) reported a randomized trial of 217 cT1–T2 patients comparing 64 Gy in 2-Gy fractions over 6.5 weeks to 55 Gy in 2.75-Gy fractions in 4 weeks. Median follow-up was 90 months and showed improved 7.5-year biochemical relapse-free survival in the hypofractionated arm (34% vs. 53%, comparatively, $P < .05$). Although this study offers support for the rationale of hypofractionation, the numbers are small and the total doses are again low.

Pollack et al. (2011) reported the results of the Fox Chase randomized study of 303 men with intermediate- or high-risk cancer. Standard fractionation was 76 Gy in 2-Gy fractions versus 70.2 Gy in 2.7-Gy fractions. There were no significant differences in 5-year biochemical failure (15% vs. 19%, *P* = .342) and worse late grade 2+ GU toxicity in the hypofractionated arm (18% vs. 8%, *P* = .028).

A randomized trial of moderate hypofractionation from MD Anderson Cancer Center randomized 204 predominantly low- and intermediate-risk men to 75.6 Gy in 1.8-Gy fractions or 72 Gy in 2.4-Gy fractions (Kuban et al., 2010). With a median follow-up of 4.7 years, 5-year freedom from biochemical failure was not significantly different (*P* = .23) between standard fractionation (92%) and hypofractionation (92%). Toxicity was likewise similar, although there was a trend toward worse late GI toxicity with hypofractionation (*P* = .058).

In the Conventional versus Hypofractionated High-dose Intensity Modulated Radiotherapy for Prostate Cancer (CHHiP) study, Dearnaley et al. (2012) randomized 3216 men with localized prostate cancer (T1b to T3a N0M0) to conventionally fractionated (74 Gy in 37 fractions) or hypofractionated (60 Gy in 20 fractions or 57 Gy in 19 fractions) RT. With a median follow-up of 62.4 months, 5-year biochemical or clinical failure–free survival was 88.3%, 90.6%, and 85.9%, respectively. With a critical HR for noninferiority set at 1.208, the 60-Gy group was noninferior to conventional fractionation (HR 0.84, 90% CI, 0.68 to 1.03), and the 57-Gy group did not meet the threshold (HR 1.2, 90% CI, 0.99 to 1.46). There were no significant differences in toxicity between groups.

Lee et al. (2016a) reported the results of RTOG 04-15, which randomized 1115 men with low-risk prostate cancer to conventionally fractionated (73.8 Gy in 41 fractions) or hypofractionated (70 Gy in 28 fractions) RT. With a median follow-up of 5.8 years and using a noninferiority threshold HR of 1.52, hypofractionation was noninferior to conventional fractionation with regard to disease-free survival (HR 0.85, 95% CI, 0.64 to 1.14). Hypofractionation was associated with increased late grade 2 and 3 GI and GU side effects (HR 1.31 to 1.59).

In the Hypofractionated versus Conventionally Fractionated Radiotherapy for Patients with Localised Prostate Cancer (HYPRO) trial, 804 men with intermediate- to high-risk prostate cancer were randomized to receive 78 Gy in 39 fractions or 64.6 Gy in 19 fractions (3 days per week) (Incrocci et al., 2016). At 60 months median follow-up, hypofractionated RT was not superior to conventional fractionation for relapse-free survival (adjusted HR 0.86, 95% CI, 0.63 to 1.16, $P = 0.36$).

Finally, the Prostate Fractionated Irradiation Trial (PROFIT) through the Ontario Clinical Oncology Group randomized 1206 men with intermediate-risk prostate cancer to conventionally fractionated (78 Gy in 39 fractions) or hypofractionated (60 Gy in 20 fractions) RT (Catton et al., 2017). With a noninferiority HR less than 1.32, they found hypofractionation to be noninferior (HR 0.96, 90% CI, 0.77 to 1.2) with regard to biochemical-clinical failure. Additionally, they found no significant differences in grade ≥3 late GI or GU toxicity.

In summary, multiple large randomized trials comparing conventionally fractionated and hypofractionated RT suggest that hypofractionation provides similar outcomes while shortening treatment courses. Patients should be advised, however, that there may be an increased risk for acute GU and GI toxicity associated with higher dose-per-fraction regimens.

Studies of ultrahypofractionation are largely limited to phase I/II studies (Table 157.10). King et al. (2013) performed a pooled analysis of prospective phase II trials at 8 institutions and including 1100 patients with low- (58%), intermediate- (30%), and high-risk (11%) prostate cancer who received prostate SBRT. With a median follow-up of 36 months, 5-year biochemical relapse–free survival was 95%, 84%, and 81% for low-, intermediate-, and high-risk disease, and neither total dose nor use of ADT had a significant influence on outcome in any risk group. Some studies have shown a marked increase in late morbidity compared with studies of moderate hypofractionation, with grade 2 urinary toxicity in some studies greater than 30%. Although it is a rare occurrence, one study did note a grade 4 rectal ulcer in a patient receiving 50 Gy in 5 fractions (Boike et al., 2011), and another reported a rectal fistula (Loblaw et al., 2013).

Data from Katz and Kang, 2014.

There is one phase III trial of ultrahypofractionation, the Swedish ISRCTN 4590531 or “HYPO-RT-PC” trial, which has randomized intermediate-risk men to 78 Gy in 2-Gy fractions with 42.7 Gy in 6.1-Gy fractions. Preliminary toxicity data (Widmark et al., 2016) suggest that ultrahypofractionation may carry an increased risk for acute GI toxicity (9.4% vs. 5.3%, $P = 0.23$) at end of treatment but no differences in toxicity at 2 years. Primary outcomes data are forthcoming.

The use of moderate hypofractionation for postoperative RT has been studied in multiple retrospective and phase I/II studies. Siepe et al. (2018) recently completed a comprehensive review of this literature and found 17 published reports of 1208 men treated with hypofractionated RT after prostatectomy. The majority of these studies described fewer than 50 patients, median follow-up was 30 months, and treatment regimens varied across studies. Overall no acute ≥grade 3 GI toxicity was reported, and late ≥grade 2 toxicity ranged from 0% to 9%; acute ≥grade 3 GU toxicity was similarly rare, ranging from 0% to 3%. Reports of late ≥grade 2 GU toxicity varied from 0% to 66% (median 12%) without a single clear etiology for the level of variability. Disease outcomes in this setting are difficult to contextualize given the heterogeneous landscape of the available studies, and prospective randomized trials are needed.

Key Points: Hypofractionation and Stereotactic Body Radiation Therapy

- Hypofractionation reduces the overall treatment course by delivering higher doses per fraction. Safe treatment delivery requires accurate patient setup and conformal treatment planning.
- Doses in the range of 2.4 to 3.4 Gy have been delivered in phase III trials with low morbidity. Patient risk selection and biologically effective doses have resulted in excellent biochemical control reported up to 5 years, but it

is not clear if moderate hypofractionation is more efficacious.

- Early studies of ultrahypofractionation (7 to 10 Gy) show good biochemical control rates, but the duration of follow-up is limited. Toxicity rates vary. Larger phase III trials are needed.

Outcomes for Brachytherapy

Post-treatment biopsies can be used to assess the efficacy of local therapies to control cancer, but there are several limitations to using this technique in prostate cancer, which were discussed earlier in this chapter. Early studies of prostate brachytherapy included postimplantation biopsy; these studies showed a very low rate of 4% to 5% positive biopsy results 2 years after good dosimetry implants (Prestidge et al., 1997; Stone et al., 2004). More recently, biochemical surrogates for cancer control have been used in addition to survival parameters.

Serum PSA is the most useful marker to assess relapse. A rising PSA level after irradiation predicts local or distant relapse, or both, often many years before clinical evidence of recurrence (Kaplan et al., 1993). However, the variability of PSA, especially at low levels, often makes interpretation problematic. In addition, the suppression of PSA with even short courses of ADT can complicate the interpretation of results. A PSA bounce has been reported in approximately 30% of patients after brachytherapy (Critz et al., 2000; Hinnen et al., 2012). Some investigators have reported improved rates of cancer control in patients who experience a PSA bounce (Hinnen et al., 2012; Patel et al., 2004).

Comparative Efficacy of External Beam Radiation Therapy Versus Brachytherapy

Goy et al. (2016) retrospectively compared 93 patients treated with ^{125}I brachytherapy to 145 Gy and 597 patients treated with EBRT (median dose 75.3 Gy) during the same period. All patients had intermediate-risk prostate cancer. With a median follow-up of 7.8 years, 10-year freedom from biochemical failure was 81.7% for brachytherapy versus 54.5% for EBRT ($P = 0.002$), though there were no significant differences in distant metastasis-free, disease-specific, or overall survival. Neoadjuvant ADT was utilized in 10.8% of brachytherapy patients versus 59.5% of EBRT patients. Although patients receiving brachytherapy were younger and generally had less aggressive disease, brachytherapy remained an independent predictor of freedom from biochemical failure after propensity score–matched multivariate analysis.

In a retrospective comparison of 950 patients treated with brachytherapy and 785 patients treated with EBRT (484 treated to < 72 Gy and 301 ≥ 72 Gy), Kupelian et al. (2004) found that all patients had localized disease (cT1 to T2) and comprised all risk categories by PSA and Gleason score criteria. After multivariate analysis, EBRT to < 72 Gy was associated with inferior 5- and 7-year biochemical recurrence–free survival, but otherwise treatment modality was not associated with outcome. This study also found no difference in outcome for RP or combined EBRT and brachytherapy.

Table 157.11 summarizes the clinical outcomes of permanent implant monotherapy in several large series, which also provide comparisons against same-institution results with EBRT. Although these are retrospective single-institution studies, they represent results from a uniform population of patients. As seen, these results compare favorably with those of similarly selected patients treated with EBRT. However, to date no randomized trials have directly compared brachytherapy alone versus EBRT alone. Early results with HDR monotherapy for patients with low-risk prostate cancer have demonstrated acceptable toxicity and early rates of biochemical freedom from relapse similar to those for permanent seed implants. Table 157.12 summarizes the results of trials of HDR monotherapy.

Brachytherapy Combined With External

Irradiation

Biochemical disease–free survival for high-risk men using this strategy can range from 80% to 90%, particularly when combined with ADT (Koontz et al., 2009; Merrick et al., 2011; Shilkrut et al., 2013a, 2013b; Taira et al., 2010). HDR brachytherapy series with at least 5 years of follow-up also show very good biochemical control for both intermediate-risk (83% to 100%) and high-risk (74% to 91%) patients (Morton and Hoskin, 2013).

The role of external beam with permanent seed brachytherapy versus brachytherapy alone for selected intermediate-risk men was investigated in the randomized clinical trial RTOG 0232 (Prestidge et al., 2016). This study randomized men with intermediate-risk prostate cancer (clinical T1c to T2b by the *American Joint Committee on Cancer (AJCC) Cancer Staging Manual*, 6th edition, Gleason 2 to 6 and PSA ≥10 but <20 or Gleason 7 and PSA <10) to prostate brachytherapy alone (^{103}Pd to 125 Gy or ^{125}I to 145 Gy) or partial pelvis EBRT (45 Gy) followed 2 to 4 weeks later by brachytherapy (^{103}Pd to 100 Gy or ^{125}I to 110 Gy). In the initial report at 5 years, no difference in freedom from progression was measured, but brachytherapy alone resulted in lower rates of late toxicity Grade ≥2 (37% vs. 53%, $P = 0.0001$ and late grade ≥3 (12% vs. 7%, $P = 0.039$). Of note, this study did not stratify into favorable and unfavorable intermediate risk, and also allowed for use of ADT at each investigator's discretion, so there are some potential confounding factors in the trial.

The ASCENDE-RT trial compared EBRT alone to EBRT with a brachytherapy boost in intermediate- and high-risk prostate cancer (Morris et al., 2017). In this trial, 398 men were enrolled, stratified by NCCN risk group, and randomized to treatment groups. All men received 12 months of ADT beginning 8 months before RT, followed by EBRT to 46 Gy to the prostate, seminal vesicles, and regional nodes. The EBRT-alone group then received an additional 32 Gy prostate boost, and the EBRT plus brachytherapy group received a ^{125}I implant to 115 Gy delivered 2 to 3 weeks after EBRT. With a median follow-up of 6.5 years, EBRT alone was associated with significantly higher biochemical failure (HR 2.04, $P = 0.004$) relative to EBRT with a brachytherapy boost.

Focal Therapy for Prostate Cancer

Kae Jack Tay MBBS, MRCS(Ed), MMed(Surgery), MCI, FAMS (Urology),
Thomas J. Polascik MD

Introduction

The global incidence of prostate cancer is estimated at 30.6 per 100,000 per year and is the second most incident cancer among men (Ferlay et al., 2013). In the United States, it is the most common solid organ malignancy among men and the third leading cause of death (American Cancer Society, 2016). In a similar pattern, the incidence of prostate cancer has been observed to increase over a 10-year period, particularly in countries with a high human development index and per capita gross domestic product (Wong et al., 2016). Much of the controversy that has arisen regarding prostate cancer overdiagnosis and overtreatment is a result of the concern that many more men have been exposed to the side effects of traditional radical treatments than necessary. Although these treatments have been highly effective in the oncologic sense, there is often collateral damage to the surrounding cavernosal nerves, urinary sphincter, and other adjacent organs (Resnick et al., 2013). Tools for early detection of prostate cancer such as multiparametric magnetic resonance imaging (mpMRI) and MRI-fusion targeted biopsies, as well as the recognition that Gleason grade 4 and 5 cancers are the biologically lethal subgroup of cancers, have now led to an interest in the use of gland-sparing targeted therapies to achieve oncologic control with less morbidity (Mendez et al., 2015).

Concepts and Historical Perspective

The idea of prostate focal therapy followed on the heels of the successful paradigm shift in breast cancer treatment among breast surgeons. The traditional Halsted mastectomy had given way to breast preservation utilizing local excision and reconstructive techniques. Early attempts in prostate gland–sparing treatments involved subtotal ablations, whereby the sparing of one, or possibly both, neurovascular bundles was attempted (Onik et al., 2002). The term *male lumpectomy* was then coined to describe hemiablation of the prostate as the first form of focal therapy (Mouraviev and Polascik, 2012; Onik et al., 2007b). Many early ablations were performed without the benefit of advanced imaging, and lesion localization techniques varied from standard transrectal biopsies to 5-mm transperineal template grids. Steady advances in technology now allow surgeons to better visualize the prostate and localize the cancer, making possible true image-guided focal destruction of the offending cancer with a margin of normal tissue.

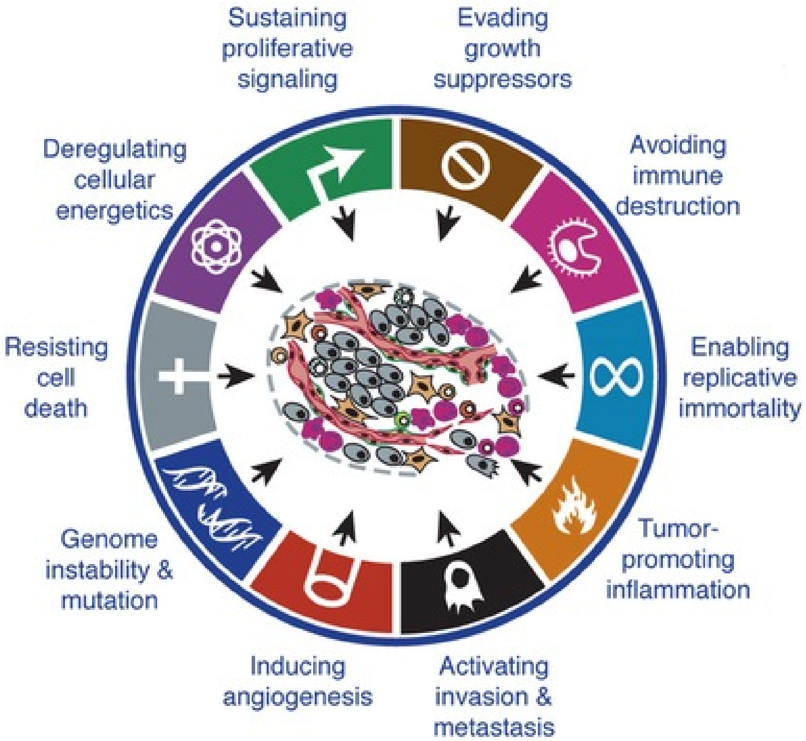
Treatment of prostate cancer is contingent on a balance between cancer aggressiveness and life expectancy. The goal of focal therapy is to treat only those foci of cancer within the prostate gland that will affect the patient's survival or quality of life while preserving surrounding tissue and structures and in turn, the patient's sexual and urinary function.

Biologic Basis for Prostate Focal Therapy

Using Cancer Grade as an Indication of Aggressiveness

Natural history studies suggest that tumor grade, serum prostate-specific antigen (PSA) levels, and clinical stage are the best predictors of prostate cancer–related mortality. Among these phenotypic expressions of aggressivity, cancer grade remains the earliest indication of lethal potential in low-volume, localized prostate cancer. A modification of the Gleason grading system described by Donald Gleason in 1973 remains the most effective and practical prognosticator of cancer aggressiveness today.

Hanahan and Weinberg famously defined the hallmarks of cancer in a 2000 review paper, further expanded in 2011, listing the acquisition of cell self-sustenance, immortality, and invading capabilities as the distinguishing features of cancer (Fig. 158.1). Gleason grade 4 and 5 cancers, compared with grade 3 cancers, do possess many characteristic molecular hallmarks of malignancy.



Sustaining proliferative signaling
Evading growth suppressors
Avoiding immune destruction
Enabling replicative immortality
Tumor-promoting inflammation
Activating invasion & metastasis
Inducing angiogenesis
Genome instability & mutation
Resisting cell death
Deregulating cellular energetics

FIG. 158.1 Emerging and established hallmark capabilities and enabling characteristics of cancer. (Modified from Hanahan D, Weinberg RA. Hallmarks of cancer: the next generation. *Cell* 144(5):646–674, 2011.)

Unopposed growth is a key feature in high-grade prostate cancers. Ross et al. (2011) described 670 genes expressed differentially between Gleason 3+3 and Gleason 4+4 cancers isolated by laser capture microdissection. These included genes involved in the developmental processes, signal transduction, and chemokine and embryonal stem cell pathways, particularly involving the androgen receptor, EGFR, TNF-alpha, and Notch signaling cascades. This explained earlier findings that *EGFR* gene copy numbers were not increased when examined using fluorescent in situ hybridization of Gleason pattern 3 and 4 areas obtained from Gleason 3+4 radical prostatectomy specimens (Skacel et al., 2001). However, the same investigators did find that aneusomy of chromosomes 7, 8, and 17 and amplification of HER-2/neu occurred almost exclusively in pattern 4 areas, further supporting the view that Gleason grade 4 carries a higher malignant potential compared with grade 3.

Loss of tumor suppression is an important cause of unopposed growth. The majority of gene deletions in prostate cancer typically involve large chromosomal segments. Kluth et al. (2017) demonstrated that the size of heterozygous deletions of 6q and 16q, the most commonly deleted segments in prostate cancer and those that contain large numbers of tumor suppressors, were highly correlated with Gleason score.

Loss of cell cycle regulation is also a prominent feature of cancers with a higher Gleason grade. Cyclin D2, a critical cell cycle regulatory gene (Susaki and Nakayama, 2007), has also been found to be inactivated via promoter methylation at greater levels where Gleason score was higher (Padar et al., 2003). Loss of cyclin-dependent kinase inhibitor p27(kip1) protein is also correlated with Gleason grade (Guo et al., 1997).

Higher Gleason grade cancers are more likely to exhibit antiapoptotic features compared with their low-grade counterparts. True et al. discovered an 86-gene panel differentiating Gleason pattern 3 from Gleason pattern 4 or 5 prostate cancer cells obtained from laser capture microdissection of radical prostatectomy specimens (True et al., 2006). Among this panel, they reported a specific finding of more intense staining in grade 4 and 5 cancers for the defender against apoptosis 1 *(DAD1)* gene, a downstream target of the NF-κB survival pathway that exhibits antiapoptotic functions (Patel et al., 2000) and has been associated with perineural invasion–associated prostate cancer in vitro (Ayala et al., 2004). Fleischmann et al. (2012), showed that *Bcl-2,* an antiapoptotic gene known to have increased gene copy numbers in androgen-independent prostate cancer, was already overexpressed in the hormone-naïve setting, and especially so in cancers with high Gleason score, advanced stage, and high proliferation index.

Aggressive cancers have also been found to have increased angiogenesis, with vessels that are primitive in morphology and function. Mucci et al. (2009), using immunostaining of CD34 to identify and measure vessel density in 572 prostatectomy tumor tissue blocks, reported that men with tumors exhibiting the smallest vessel diameter and the most irregularly shaped vessels were 5 and 17 times more likely to die from lethal cancer, respectively. Angiogenic growth factors such as VEGF/PK-1 are also progressively expressed in prostate cancer as Gleason score increases (Pasquali et al., 2006). Angiogenesis, through increased sustenance and providing a path for metastasis, contributes to the lethal potential of high Gleason grade cancers.

Metastasis is a hallmark of malignancy, and epithelial-mesenchymal transition (EMT) is thought to be an important step in the development of pathologic migratory properties. Jędroszka et al. (2017) found that the expression profiles of 43 genetic EMT markers were strongly associated with Gleason score. SRFP-4, a regulator of the Wnt signaling pathway that is implicated in carcinogenesis and EMT (Sandsmark et al., 2017b), was found to be significantly more expressed in high Gleason grade groups (Mendez et al., 2015; Resnick et al., 2013; Wong et al., 2016), lethal cancer, and metastatic prostate cancer (Sandsmark et al., 2017a).

In summary, Gleason pattern 4 and 5 demonstrate many of the hallmarks of malignancy compared with Gleason pattern 3, and these represent priority targets for elimination. In early-stage, low-volume prostate cancer, focal treatment of these areas may be able to eradicate potentially lethal cancer, with the remainder of the benign/pattern 3–bearing gland being subjected to surveillance.

Multifocality of Prostate Cancer Versus the Index Lesion Hypothesis

On pathologic examination of radical prostatectomy specimens, it appears that the majority of prostate cancer (50% to 91%) is multifocal except for one Korean study reporting a unifocal cancer rate of 67% (Song et al., 2003) (Table 158.1). However, it is thought that the index lesion, the largest tumor focus within the prostate, determines the subsequent course of the cancer (Ahmed, 2009). This hypothesis is supported by the following data:

TABLE 158.1

PSA, prostate-specific antigen; *pT2,* pathologic tumor stage.

1. **Most of the time, the grade/stage is determined by the index lesion.** In a series of 961 radical prostatectomy specimens, Ohori et al. (2006) reported that 377 lesions exhibited extracapsular extension, of which 84% were from the main or index lesion, and 16% were from nonindex lesions. Analyzing the subpopulation of 470 men with a serum PSA less than 10 ng/mL, they found that 92% of the time, extracapsular extension occurred in the index lesion only, 3% in the non-index lesions, and 5% in both.
2. **Most of the tumor volume is contributed by index lesion.** Ohori et al. (2006) reported on 961 radical prostatectomy specimens and found that the index lesion accounted for 80% of the tumor burden. In a series of 61 radical prostatectomies, Hollmann et al. (2015) reported that the index lesion accounted for 88% of total tumor volume within the prostate. Both total and index tumor volumes have been found to be important predictors of biochemical recurrence after radical prostatectomy (Shin et al., 2016), and the data suggest that the majority of intraglandular tumor volume can be dealt with by treating the index lesion.
3. **The majority of satellite tumors are small and low grade.** The definition of an insignificant cancer using <0.5 mL as a cutoff was created by Stamey et al. in 1993—a conclusion based on findings that (a) SEER data suggested a lifetime probability of significant prostate cancer to be 8% and (b) the largest 8% of cancers in the Stanford University bladder cancer cystoprostatectomy series were of the volume 0.5 to 6.1 mL. Among six radical prostatectomy series (Catto et al., 2011; Hollmann et al., 2015; Karavitakis et al., 2011, 2012; Noguchi et al., 2003; Wise et al., 2002) in which the sizes of the satellite lesions were measured, the incidence of unifocal cancer ranged from 12.4% to

25%, but when accounting for cases in which satellite lesions were <0.5 mL in aggregate, this figure rose to between 52% and 93.4%. Villers et al. (1992) found that 80% of secondary cancers were less than 0.5 mL in volume. Application of Stamey's rationale to modern series such as the Charing Cross cystoprostatectomy series or the Rotterdam arm of the European Randomized Screening for Prostate Cancer trial yields thresholds of less than 1.03 mL (Winkler et al., 2007) or <1.31 mL (Wolters et al., 2011), respectively, for clinically significant cancer. This suggests that if these small lesions of doubtful clinical significance were to be left untreated and on observation, a much larger proportion of patients would be eligible for focal therapy than the earlier pathologic data suggest.

4. **Genetic studies suggest a monoclonal origin of metastatic or lethal prostate cancer.** Besides grade heterogeneity among the multiple lesions in multifocal prostate cancer, these lesions tend to be diverse in gene mutations (Cooper et al., 2015), copy number (Ibeawuchi et al., 2013), methylation (Serenaite et al., 2015), and genetic expression (Wei et al., 2017), suggesting the presence of multiple cancer lineages within the prostate that may have differing aggressivity (Fig. 158.2). Further, Liu et al. (2009) analyzed prostate cancer metastases in autopsies of men who had died from prostate cancer and found that most, if not all, metastatic prostate cancers have a monoclonal origin and maintain a unique signature copy number pattern of the parent cancer cell while also accumulating separate subclinical, sustained changes.

In summary, if the index lesion can be accurately identified and ablated, the majority of tumor within the prostate, and its most aggressive components, can be treated. By removing the lethal component of the prostate cancer, theoretically, metastasis and death could be prevented.

On the other hand, it is important to note that pathologic features of aggression such as largest tumor size, highest Gleason score, or highest stage, do not always occur in the same nodules, and in fact, may occur in satellite rather than index lesions 12% to 38% of the time. Ruijter et al. (1996) found that 18% of index lesions had a Gleason score lower than that of adjacent nonindex lesions, and extraprostatic extension (EPE) was found in two nonindex lesions.

Arora et al. (2004) found that the Gleason score of the index lesion was correlated with the overall Gleason score in only 68% of specimens. Huang et al. (2014) found that in most of the multifocal cases (156/176 or 88.7%), the highest Gleason score, tumor volume, and presence of EPE was found in the index lesion. To further confound matters, in one case report of a man dying from metastatic prostate cancer, the lethal clone was traced back to a small, low-grade (Gleason pattern 3) focus, rather than other high-grade lesions (Haffner et al., 2013).

These biologic variations will contribute to treatment failures in focal therapy applied to the index lesion and are a reminder that close post-treatment surveillance is necessary so that salvage interventions can be undertaken in a timely manner. These same biologic exceptions can also be associated with treatment failure with conventional whole-gland approaches and also active surveillance. Nonetheless, the advances in biologic understanding have driven contemporary clinical concepts in focal therapy, which will undoubtedly continue to evolve as we further our knowledge in this area.

Clinical Applications of Focal Therapy

Treating the Index Lesion

The concept that the natural history of prostate cancer is typically driven by a primary lesion, rather than secondary lesions (Stamey et al., 2001), is being increasingly accepted. If the dangerous foci in the prostate could be eradicated, oncologic control of the cancer could be achieved while maintaining quality of life. The secondary lesions in the remainder of the prostate gland could then be placed on active surveillance.

The Complementary Roles of Focal Therapy and Active Surveillance

Two of the largest active surveillance cohorts have reached 10 to 15 years of follow-up, showing an extremely low metastasis rate among men with D'Amico low-risk prostate cancer (Klotz et al., 2015; Tosoian et al., 2015). In one of the cohorts with more inclusive criteria (up to low-volume Gleason 3+4 cancer), it was found that the majority of those in whom cancer progressed had Gleason 3+4 disease (Yamamoto et al., 2016). In the Prostate Intervention Versus Observation Trial (PIVOT), a survival benefit was seen in the intermediate-risk subgroup with prostatectomy rather than observation (Wilt et al., 2012). Indeed, Gleason grade 4 cancers appear to have many more hallmarks of cancer compared with Gleason grade 3, and likely represent the relevant therapeutic target (Klotz, 2013).

These findings support a complementary strategy of treating intermediate or high-grade cancer foci with focal therapy, while monitoring the remainder of the gland having low-grade cancer with active surveillance (Klotz and Polascik, 2014). During surveillance, if any higher-grade cancers are detected, they could potentially be treated focally again. This would provide long-term oncologic control and effectively transform prostate cancer into a chronic disease, commensurate with its long natural history.

To these ends, a successful focal strategy depends on a multidisciplinary team of uro-oncologists, radiologists, pathologists, and others to do the following:

1. Accurately determine the disease extent/location through advanced

imaging and biopsy
2. Ascertain that the patient will benefit from treatment and be compliant to follow-up
3. Completely ablate the index lesion(s)
4. Monitor the patient post-treatment utilizing advanced imaging and biopsy with a view to future targeted treatment of either persistent or de novo disease, or conversion to whole-gland treatment as necessary

Patient Selection

Patient selection is the fundamental tenet of achieving a successful focal therapy strategy. The aggressive lesion within the prostate must be identified and its extent carefully delineated to completely ablate it. Because of the small risk for infield recurrence resulting from incomplete ablation or outfield ablation caused by small satellite lesions being missed or de novo occurrence of prostate cancer in the untreated gland, the patient must be compliant, willing, and psychologically suited for close surveillance after treatment.

The lesion is first identified with a combination of histologic and/or radiologic methods. Advanced radiologic techniques such as mpMRI allow the entire prostate gland to be visualized and, in some cases, predict a more aggressive histology. However, because of limitations in current technology, there remains consensus to histologically confirm the aggressiveness of the lesion through biopsy. Furthermore, current imaging studies remain imperfect in predicting the absence of aggressive cancer, and many experts would advocate a systematic biopsy to more comprehensively evaluate the gland.

Biopsy-Based Lesion Identification

Much of the work in biopsy-based lesion localization was directed toward intraglandular cancer lateralization for the purposes of focal hemiablation. At this time, focal hemiablation was reserved primarily for low-grade cancer patients, many of whom might be placed on active surveillance today. However, the data provide a valuable insight on the ability of biopsy to accurately map cancer. Among men who had undergone radical prostatectomy, Polascik et al. (2009) showed that transrectal ultrasound-guided (TRUS) biopsy unilaterality was the strongest predictor of pathologic unilaterality, with a sensitivity of 88.4%, a specificity of 34%, and positive and negative predictive values of 28% and 91%, respectively. It seems logical that increasing the biopsy intensity would improve the performance of the biopsy in cancer detection/lateralization. Tsivian et al. (2010) showed that extended versus sextant TRUS biopsies had better specificity (53.9% vs. 37.1%) and negative predictive value (95.8% vs. 91.8%). On the other hand, Abdollah et al. (2011) showed that at 24-core TRUS biopsy, specificity in predicting unilateral disease remained at 49.4%, and positive and negative predictive values remained at 22.6% and 98.9%, respectively, suggesting that there was a limitation strategy of increasing the number of biopsy cores transrectally. This may be caused by the inherently random nature of the TRUS systematic biopsy and poor access to the anterior zone of the prostate gland through a transrectal approach.

In the 1990s, many operators turned to transperineal mapping biopsy (TMB) to overcome these limitations. The transperineal approach allows equal access to the anterior and posterior prostate gland. The use of a 5-mm grid or a systematic biopsy template ensures a consistent biopsy intensity as well as distribution of biopsy cores. Barzell and Melamed (2007) showed that staging (TRUS) biopsies had a false-negative rate as high as 47% and a sensitivity and negative predictive value as low as 54% and 49%, respectively, compared with TMB in determining suitability for hemiablative cryotherapy (Barzell and Melamed, 2007). Onik and Barzell (2008) reported that among 110 men with unilateral cancer defined on TRUS biopsy, more than one-half were disqualified after undergoing TMB.

Several groups have attempted to create predictive models combining biopsy and other clinical parameters to accurately predict cancer laterality. Fu et al. (2012), in a cohort of 1495 men, found that only PSA less than or equal to 4 ng/mL and unilateral cancer on biopsy were significant factors in predicting unilateral disease at radical prostatectomy. Gallina et al. (2012) were unable to develop a model in a cohort of 321 men, finding only that the number of positive cores was significant with an AUC of 0.52. Truesdale et al. (2010) found that an increased burden on TRUS biopsy (≤2 vs. >2 positive cores) led to a greater likelihood to experience pathologic persistence of cancer or biochemical recurrence after focal treatment. Most of the data presented in this section were obtained with the objective of predicting the location of all, including low-risk, cancer. There is current interest in preferential detection of Gleason pattern 4 and 5 cancers—thought to be the culprits in prostate cancer progression, metastasis, and mortality—rather than Gleason pattern 3 cancers that are suitable for active surveillance and the excessive detection of which may lead to overtreatment.

Advanced Imaging Techniques in Prostate Cancer

Multiparametric Magnetic Resonance Imaging

Improvements in MRI technology such as high field-strength magnets, development of MRI contrast agents, and improved MRI protocols have improved the resolution of anatomic imaging and led to the addition of functional imaging, leading to multiparametric or mpMRI, which has a high diagnostic accuracy. These developments have positioned mpMRI as a key enabler for prostate focal therapy and have been responsible for renewed interest in this area because of its ability to do the following:

1. **Preferentially detect high-grade lesions.** Dynamic contrast-enhanced (DCE) imaging using gadolinium-based MRI contrast is highly sensitive to vascularized lesions and preferentially detects larger and higher-grade cancer foci (Arumainayagam et al., 2013; Rosenkrantz et al., 2012). Diffusion-weighted imaging (DWI) quantifies the mobility of water molecules to highlight regions with high cellular density that are often correlated with the loss of glandular architecture in high-grade cancer (Gupta et al., 2013).
2. **Improve the detection of anterior zone prostate cancers.** Anterior-zone cancers, accounting for 15% to 33% of prostate cancers in cystoprostatectomy series (Nevoux et al., 2012) and radical prostatectomy series (Al-Ahmadie et al., 2008; Bott et al., 2002), are generally diagnosed at a late stage because the location is relatively inaccessible to TRUS biopsy. Anterior-zone cancers are readily detected (Komai et al., 2013) and characterized on mpMRI (Ouzzane et al., 2011). If done so at an early stage, these are ideal lesions for focal therapy as they are amenable to complete ablation while sparing both neurovascular bundles (Tay et al., 2016a).
3. **Improve the detection of EPE.** Contemporary mpMRI series report an accuracy of 62% to 74%, a sensitivity of 35% to 63%, a specificity of 73% to 91%, a positive predictive value of 36% to 85%, and a negative

predictive value of 57% to 92% in the detection of EPE (Cerantola et al., 2013; Feng et al., 2015; Kayat Bittencourt et al., 2015; Raskolnikov et al., 2015; Somford et al., 2013). mpMRI staging has also been shown to outperform the Partin tables in predicting pathologic EPE (AUC 0.88 vs. 0.70) (Gupta et al., 2016).

4. **Accurately identify the index lesion.** Le et al. (2015) evaluated 122 men with preprostatectomy mpMRI and reported that although the overall mpMRI sensitivity for tumor detection was 47%, this increased to 72% for larger (>1 cm), 72% for higher-grade (Gleason ≥7), and 80% for index tumors. Baco et al. (2015), in an analysis of 135 men, demonstrated that the concordance between the index tumor location on mpMRI and radical prostatectomy specimens was 95%. Delongchamps et al. (2015) evaluated 125 men undergoing presurgical MRI fusion biopsy and reported that mpMRI failed to detect 95 cancer foci, of which the 14 that were clinically significant harbored only 1 index lesion, with the remainder harboring <20% pattern 4.

Despite the vast improvements brought with the advent of mpMRI, it is important to note that the technique remains imperfect. The PROMIS study, comparing mpMRI to a 5-mm grid TMB, reported a sensitivity for clinically significant cancer of 93%, a specificity of 41%, a positive predictive value of 51%, and a negative predictive value of 89% (Ahmed et al., 2017). The strength of this study was that it encompassed 11 centers with varying types of equipment and levels of radiologist expertise. Indeed, mpMRI performance is subject to technical variations such as magnetic coil strength (3 Tesla is more accurate than 1.5 Tesla) (Chang et al., 2008), the use of an endorectal coil (recommended to augment field strength when using 1.5 Tesla) (Hricak et al., 2007), and the scanning protocol. Accurate index lesion identification (Gaziev et al., 2016) and interpretation of EPE (Tay et al., 2016b) are heavily dependent on reader experience. The PROMIS data suggest that mpMRI lesions require histologic confirmation, systematic biopsies of mpMRI-negative areas may not yet be omitted, and a treatment approach heavily reliant on mpMRI may result in a small but not insignificant number of outfield recurrences.

Complete treatment of the index lesion would require an accurate estimation of its three-dimensional volume with the addition of a safety margin. Historadiologic correlation studies consistently show that mpMRI underestimates histologic tumor volume by 5% to 30%, after accounting for shrinkage and other artifacts (Baco et al., 2015; Cornud et al., 2014; Le Nobin et al., 2015; Priester et al., 2017; Radtke et al., 2016; Rud et al., 2014; Turkbey et al., 2012). Furthermore, Priester et al. (2017) reported that the mean axial diameter of an index lesion is underestimated by 11 mm. However, it is not known if the degree of underestimation would be reduced if only pattern 4 and 5 areas were taken into consideration. Nonetheless, this poses significant challenges for lesion-based ablation, and complete ablation may ultimately require hemiablation or zonal ablation.

MRI-Targeted/Fusion Biopsy

Because of the high sensitivity but low specificity of mpMRI, histologic confirmation of suspicious lesions remains critical. The American College of Radiology and European Society of Urogenital Radiology have jointly developed a grading system known as PI-RADS (Prostate Imaging–Reporting and Data System) (Barentsz et al., 2012), which is now in its second iteration (ACR, 2015). This 5-point Likert scale primarily aids radiologists in identifying clinically significant cancer, and data suggest that as the PI-RADS score increases, the higher the Gleason score of the lesion tends to be (Jordan et al., 2018). Nonetheless, at this point, histologic confirmation of the Gleason score as a marker of lesion aggressiveness remains important in clinical decision making. A 2016 consensus on patient selection for prostate focal therapy defined Gleason 3+4 lesions as the “sweet spot” for focal therapy (Tay et al., 2017d). With higher-grade lesions, there is a concern about increasingly aggressive cancer portending a higher likelihood of EPE outside the image-guided target zone that may need to be met with more radical types of treatment.

In-bore MRI-guided biopsy is performed using live MRI guidance within the MRI machine itself. Such procedures carry high accuracy but are time-consuming, costly, require specialized MRI-compatible equipment, and tend to be available only in academic centers.

MRI-TRUS fusion biopsy is a technique in which the biopsy is performed in a standard ultrasound-guided fashion but with the MRI targets overlaid onto the ultrasound image. There are now several commercial systems offering various approaches (transrectal or transperineal) to MRI fusion biopsy (Kongnyuy et al., 2016). These typically create an MRI three-dimensional prostate (MRI segmentation) and an ultrasound three-dimensional prostate (ultrasound segmentation), which are then overlapped (registration) to translate the mpMRI lesions onto the ultrasound model using either rigid or elastic deformation to match the two. The probe/needle guide is then navigated toward the lesion by the operator using mechanical, visual, or combined assistance, and the biopsy is performed. However, software fusion has a learning curve as well because the overlay of the magnetic resonance image onto the ultrasound image is often imperfect, and the user has to compensate accordingly to achieve an accurate biopsy (Tay et al., 2016c).

Another approach is to perform visual estimation targeting (VET), or cognitive/mental fusion, in which the operator estimates the position of the suspicious lesion based on its appearance on the mpMRI. In expert hands, this has been shown to be as good as software fusion (Wysock et al., 2014). Ultimately, patients can only be identified accurately for focal therapy by an experienced multidisciplinary team of radiologists and urologists. Such a team who will mount the learning curve together is a critical component of a focal therapy program.

Promising Imaging Modalities

Positron Emission Tomography (PET)

Positron emission tomography (PET) with choline-based tracers or fluorodeoxyglucose has been investigated for use in prostate cancer staging (Umbehr et al., 2013). Prostate-specific membrane antigen (PSMA) is a type 2 transmembrane protein that is expressed 100- to 1000-fold in prostate cancer cells compared with normal cells. This led to much early interest in the application of radioisotope-labeled molecules linked to PSMA in imaging for prostate cancer. Ultimately, preoperative ^{111}In-capromab pentatide correlated to radical prostatectomy failed to reliably localize prostate cancer for quadrant focal ablation (Mouraviev et al., 2009).

More recently, the development of small molecules targeting the external epitope of PSMA has led to ligands radiolabeled with ^{18}F or ^{68}Ga that are associated with high levels of accumulation within tumor tissue and rapid clearance from nontarget tissue, leading to high contrast for improved prostate cancer detection compared with early PSMA-linked radiotracers (Eder et al., 2012). One potential advantage of PSMA PET over mpMRI is that interpretation is not influenced by biopsy-related artifacts such as hemorrhage or inflammation (Eiber et al., 2015). Rowe et al. (2015) reported in 13 patients that although mpMRI had a greater sensitivity for prostate cancer, ^{18}F-DCFBC PET had a higher specificity overall and for detection of high-grade lesions (Gleason 8 and 9) confirmed on radical prostatectomy. Additionally, although mpMRI interpretation is transiently impaired by early biopsy-related artifacts such as hemorrhage or inflammation, PSMA PET does not appear to have such a limitation. Bonnal et al. demonstrated that it was feasible to fuse both choline-PET and mpMRI targets to three-dimensional TRUS to take advantage of the excellent anatomic resolution of mpMRI as well as functional PET information to define a target for biopsy (Bonnal et al., 2017).

Multiparametric Ultrasonography

Because of the resource intensity of mpMRI along with the limitations of fusion (Tay et al., 2016c), there is now significant interest in extending the capabilities of ultrasonography. Ultrasonography is already a widely available real-time technique that can be performed at the point of care, and multiparametric ultrasonography could remove the potential pitfalls associated with the MRI-ultrasound fusion process and target registration. Contrast-enhanced (CE) TRUS produces a detailed image of microvascular distribution within the prostate using highly echogenic microbubble contrast agents that are minute enough to flow within capillaries. TRUS elastography evaluates the distribution of tissue stiffness within the prostate by measuring the properties of a reflected mechanical wave. Further refinements in this area include shear wave elastography (SWE) in which the mechanical wave is no longer operator dependent, but a reproducible signal that is produced by the ultrasound probe itself. Using SWE, Boehm et al. (2015) reported a sensitivity of 80.9% and specificity of 69.1% for cancer detection using a cutoff of 50 kPa compared with whole-mount examination of radical prostatectomy specimens. Palmeri et al. (2016) explored the use of acoustic radiation force impulse (ARFI) imaging, a technique in which the generated waves occur in a synchronized fashion to eliminate interference from subsequent unwanted internally reflected waves, and found a good correlation with mpMRI in a preliminary study of 29 patients.

A multiparametric approach to ultrasonography would encompass the strengths of the individual modalities, and this combination providing functional information may improve on the sensitivities of individual modalities by 13% to 59% (Postema et al., 2015). There is a need for further prospective work in this area. Computerized TRUS (C-TRUS), first explored for quantifying gray-scale TRUS images in the 1990s, is a technique in which the ultrasound image is transformed into digital signals for statistical analysis. With the aforementioned advances in ultrasound imaging, a wealth of data are now available for correlation to pathology that could pave the way for multiparametric ultrasonography driven by artificial intelligence in the near future.

Contemporary Patient Selection Criteria

There has been a constant evolution in the criteria for patient selection because of the rapid advances in knowledge and biologic understanding of prostate cancer in the past two decades since focal therapy was first explored. Indeed, many early focal therapy cohorts included men with low-risk prostate cancer who would today be considered candidates for active surveillance. Furthermore, there have been few comparative trials between various modalities in prostate cancer because of the highly patient-centric nature of treatment selection. As a result, there is a paucity of data for which to guide development of patient selection criteria for prostate focal therapy, and the majority of focal therapy practice has been shaped by a consensus-based approach (Table 158.2).

TABLE 158.2

Summary of Contemporary Consensus on Patient Selection

YEAR OF CONSENSUS		**2010**	**2012**	**2013**	**2016**

mpMRI, multiparametric magnetic resonance imaging; *TMB,* transperineal mapping biopsy.

In a 2009 consensus meeting, the stated aim of focal therapy was to eradicate all known prostate cancer while preserving uninvolved tissue to spare genitourinary function (de la Rosette et al., 2010). Later, a 2010 consensus stated that the aim of focal therapy was to treat cancer and leave intact the benign prostate and surrounding normal structures (Ahmed et al., 2012). By 2013, the consensus was that the aim was to treat the dominant or index lesion (Donaldson et al., 2015). Here, residual untreated disease was first quantified, with the panel agreeing that it was acceptable not to treat lesions of Gleason grade 3+3 up to a length of 5 mm, though the issue of the type or intensity of biopsy necessary was not addressed. In yet another consensus panel in 2016, a Gleason 3+4 lesion, when capable of being completely ablated, was determined to be the “sweet spot” for focal therapy (Tay et al., 2017d). This panel also suggested Gleason 4+3 as a maximum grade for focal therapy, with most members reluctant to extend the role of focal therapy to high-grade cancers.

Recommendations for the best approach to patient assessment have evolved as well. In the 2010 consensus, mpMRI was recommended only in state-of-the-art centers, but in the 2016 consensus, it was recommended as far as possible. In 2010 and 2012, TMB was considered state-of-the-art, and in the 2016 consensus, MRI-TRUS fusion biopsy was the recommended modality for evaluating a suspicious lesion. Notably, the most recent consensus still recommends a systematic biopsy to evaluate the mpMRI “normal” prostate, recognizing that though mpMRI represents an advancement in prostate imaging, it still has a small but significant false-negative rate.

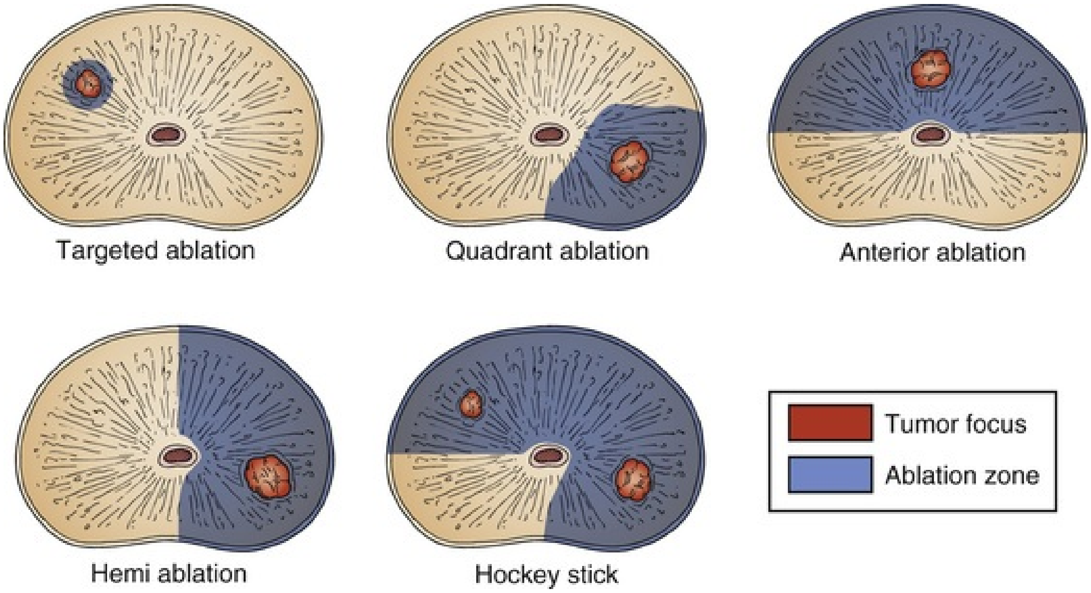
Sexual function was addressed in the 2016 consensus on patient selection and another 2013 consensus on focal therapy trial design in which the expert panels found that erectile dysfunction was not a contraindication to prostate focal therapy. In the 2016 consensus, although the expert panel agreed that the potential for preservation of erectile function is an important reason to choose focal therapy over other modalities, the majority of the experts would not deny focal therapy to a man who was already impotent. This may be a result of increasing awareness of the impact of urinary, rectal, or other toxicities that may be associated with the indiscriminate use of whole-gland therapy.

Ultimately, treatment selection for prostate cancer remains a complex interplay of disease characteristics and patient factors. Advances and improvements in the tools available to select patients have improved confidence in the ability to recommend focal therapy to a suitable subset of patients. Further research is needed to determine the most effective strategy to identify patients for focal therapy, keeping in mind the cost and morbidity of treating recurrent cancer that might arise as a result of poor selection.

Ablation Patterns and Current Technologies

Types of Ablation

Many different ablation patterns have been termed *focal therapy*, leading to significant heterogeneity within the focal therapy literature. Some of these techniques, such as “hockey stick” type ablations, would be more appropriately classified under the umbrella term of *partial prostate ablation* (Fig. 158.3). In an international consensus meeting on definitions in focal therapy, Postema et al. (2016) reported that focal therapy should include treatment of a lesion, quadrant ablation, and hemiablation. Some authors would further argue that treatment of a lesion can be further classified into image-targeted lesion ablation versus non–image-targeted ablation, whereby the lesion is treated based on biopsy information.



Targeted ablation
Quadrant ablation
Anterior ablation
Hemi ablation
Hockey stick

Ablation zone

FIG. 158.3 Patterns of ablation.

Ablation Approach

The prostate can be accessed for ablation via a transrectal, transperineal, or less commonly, a transurethral approach. The approach chosen will depend largely on the following:

1. Location of the tumor
2. Desired ablative technology that is available
3. Any other anatomic consideration unique to the patient

Transrectal approaches allow for ease of access to the posterior zone, and transperineal approaches offer better access to the anterior zone of the prostate. Cryoprobes and electrodes for irreversible electroporation (IRE) are typically constructed of metal and are at least 17-gauge in size, making them less suited for a transrectal approach. High-intensity focused ultrasonography (HIFU) is produced within an ultrasound transducer that, because of necessary housing of sufficient transducer rings to produce the desired intensity/focal distance (Constanciel et al., 2013), is usually introduced transrectally. Laser energy, on the other hand, is delivered through highly flexible fibers that can be delivered through either transrectal or transperineal routes. Ultimately, as urologists become conversant with multiple techniques, an “à la carte” approach may be adopted, where the modality/delivery combination is adapted to the patient/lesion (Sivaraman and Barret, 2016).

Cryotherapy

Cryotherapy is a thermal ablative modality achieving cell kill through extraction of heat producing lethal cold temperatures. Cryosurgery kills target tissues via physical and physiologic changes including mechanical forces resulting in membrane disruption created by intracellular and extracellular ice formation, recrystallization, vascular stasis/ischemia, apoptosis, and immune effects (Baust et al., 2014). Although it has been in use for the past two decades, recent developments have made it increasingly suited for focal therapy. First, the new third-generation cryoprobes utilizing the Joule-Thomson effect to generate lethal ice are as fine as 17-gauge, allowing them to be maneuvered to the appropriate position within the prostate. Second, variable ice length adjustment allows the ice ball to be contoured exactly to the lesion that is to be ablated. Third, the ice edge can be clearly seen using TRUS (Onik et al., 1988), CT, or MRI, and thus the extent of ablation and the ablation margin can be monitored and adjusted in real time by the treating urologist. Fourth, the use of a urethral warmer has greatly reduced the risk for urethral complications arising from cold injury to the urethral mucosa (Cespedes et al., 1997; Donnelly et al., 2001; Vellet et al., 1997). Typically, thermocouples are placed within the intended ablation zone or its margin, along vital structures such as the external sphincter, neurovascular bundles, or Denonvilliers fascia to monitor temperatures in real time (Wong et al., 1997). Excerpts of a video depicting the steps of focal cryotherapy in the form of anterior prostate cryoablation are shown in Fig. 158.4.

FIG. 158.4 Focal cryoablation procedure. (A) Biplanar ultrasound probe is placed in the rectum. (B) Variable length cryoprobes are set to prostate measurements. (C,D) An anterior ablation pattern is being used here with four probes in the anterior prostate. (E) The ice in the anterior prostate. The leading ice edge has a hyperechoic rim and can be monitored easily. (F) Console readout showing lethal temperature in the anterior apex and safe temperatures in the external sphincter *(ES)* and the right neurovascular bundle *(RNVB).* The full video may be viewed at http://www.liebertpub.com/videourology. (From Tay KJ, Polascik TJ.

Anterior prostate cancer cryoablation: a technique in prostate focal therapy, *Videourology* 31:2, 2017.)

Tay and Polascik (2016) reviewed nine contemporary cohort studies of prostate focal cryotherapy (Table 158.3). The majority of studies used a hemiablation template, as that was the original model of focal therapy for prostate cancer (Onik et al., 2007b). Over a median follow-up between 13 and 63 months, the biochemical progression–free survival (BPFS) rate was 71% to 98%. Among five cohorts (total of 272 men) that mandated a rebiopsy between 6 and 12 months, the compliance rate was 79%, and the positive biopsy rate was 21.8%, one-fourth of which were clinically significant cancer. As demonstrated in the table, biopsy criteria for patient selection before therapy and post-treatment biopsy varied across studies. Also, D'Amico risk groups were mixed, but the vast majority of patients treated with focal cryotherapy were of low- and intermediate-risk groups. The reported post-treatment pad-free continence and potency rates were 96% to 100% and 58% to 100%, respectively. Approximately one-half of patients reporting potency after hemiablation utilized phosphodiesterase type 5 inhibitors (PDE5Is) (Ellis et al., 2007). The reported rate of rectourethral fistula, the most feared complication after cryotherapy, was 0% to 0.1%.

[a] This was a Cryo On-Line Data (COLD) registry series.

BCR, biochemical recurrence; *BPFS,* biochemical progression–free survival; *DRE,* digital rectal examination; *IIEF,* international index for erectile function; *mpMRI,* multiparametric magnetic resonance imaging; *NR,* not reported, *NA,* not applicable; *PSA,* prostate-specific antigen; *TRUS,* transrectal ultrasonography; *TMB,* transperineal mapping biopsy.

There are no studies comparing focal cryotherapy to established treatments such as radical prostatectomy or radiation. One study compared partial- to whole-gland cryotherapy using a matched pair analysis in patients with low-risk prostate cancer in the Cryo-Online Data (COLD) registry (Mendez et al., 2015). No difference was observed in 60-month BPFS, and the rates of erectile recovery were noted to be significantly better with partial ablation (68.8% vs. 46.8%). A second study used propensity score matching to compare partial- to whole-gland cryotherapy in patients from the same registry with intermediate-risk prostate cancer (Tay et al., 2017a). This study reflects a more contemporary approach to selecting focal cryoablation for patients with intermediate-risk disease. There was no difference observed in early BPFS, and those receiving partial ablation were 2.1 times as likely to recover erectile function by 12 months compared with those undergoing whole-gland cryoablation (46.8% vs. 29.5%, $P = .001$).

High-Intensity Focused Ultrasonography

A transducer focuses multiple ultrasound beams onto a preset point, generating a temperature of at least 55°C (Hildebrandt et al., 2002; Napoli et al., 2013) to produce coagulative necrosis within the desired target. The transducer is typically built into the TRUS probe, which is also used for treatment planning and monitoring. Transrectal HIFU is well suited for treatment of posterior-zone lesions. However, the anterior gland may be more difficult to treat because of energy dissipation over the intervening prostate tissue and displacement of anterior zone targets with gradual edema of the prostate tissue as treatment progresses (Clyne, 2013; Shoji et al., 2013; Sivaraman and Barret, 2016). Typically, there are restrictions based on which prostates are ideal for treatment matched to a particular HIFU technology, with such limitations as prostate size, height, and calcifications in the treatment zone. Also, to better allow targeting and reduction of prostate height, some would recommend that transurethral resection of the prostate (TURP) be performed before HIFU treatment. Finally, although whole-gland HIFU takes some time to accomplish, it is well-suited to focal therapy as the treatment time is shorter.

The majority of focal HIFU series are hemiablative and rely on cognitive or software MRI fusion. El Fegoun et al. (2011) first reported a series of 12 men who underwent biopsy-directed HIFU hemiablation with a median follow-up of 127 months. They reported that the recurrence-free rate was 90% at 5 years and 38% at 10 years, with an overall 41.7% positive biopsy rate, though notably, 10 of 12 men had low-risk cancer, and most treatments were carried out in the pre-MRI era. Six more recent cohorts reported using mpMRI as a patient selection tool (Ahmed et al., 2015; Feijoo et al., 2016; Ganzer et al., 2018; Rischmann et al., 2017; van Velthoven et al., 2016). Of these, the French hemiablation trial is the largest series, with 111 men. Three of these with mandatory post-treatment rebiopsy at 6 to 12 months reported an infield positive biopsy rate of 15.5% to 34.6% for all cancer and 8.2% to 11.5% for clinically significant cancer, and an outfield positive biopsy rate of 7.7% to 36.7% for all cancer and up to 2% for clinically significant cancer (Ahmed et al., 2015; Feijoo et al., 2016; Ganzer et al., 2018). Overall post-treatment recovery of erectile function seems to vary between 60% and 78% (Table 158.4).

[a] The majority of men were not interested in sexual function in this study.

BCR, biochemical recurrence; *BPFS,* biochemical progression–free survival; *DRE,* digital rectal examination; *IIEF,* international index for erectile function; *mpMRI,* multiparametric magnetic resonance imaging; *NR,* not reported; *NA,* not applicable; *PSA,* prostate-specific antigen; *TRUS,* transrectal ultrasonography; *TMB,* transperineal mapping biopsy.

In-bore MRI-guided focused ultrasonography (MRgFUS) allows for monitoring of treatment temperatures within the target area using MR thermometry, as well as ensuring safe temperatures in the urethra and sphincter (Fig. 158.5). Tay et al. (2017c) reported a phase II clinical trial of MRgFUS, finding a slight insignificant deterioration of Expanded Prostate Cancer Index Composite (EPIC) urinary symptoms score at 1 month that returned to baseline at 3 months with no changes in other EPIC subdomain scores over a 2-year period.

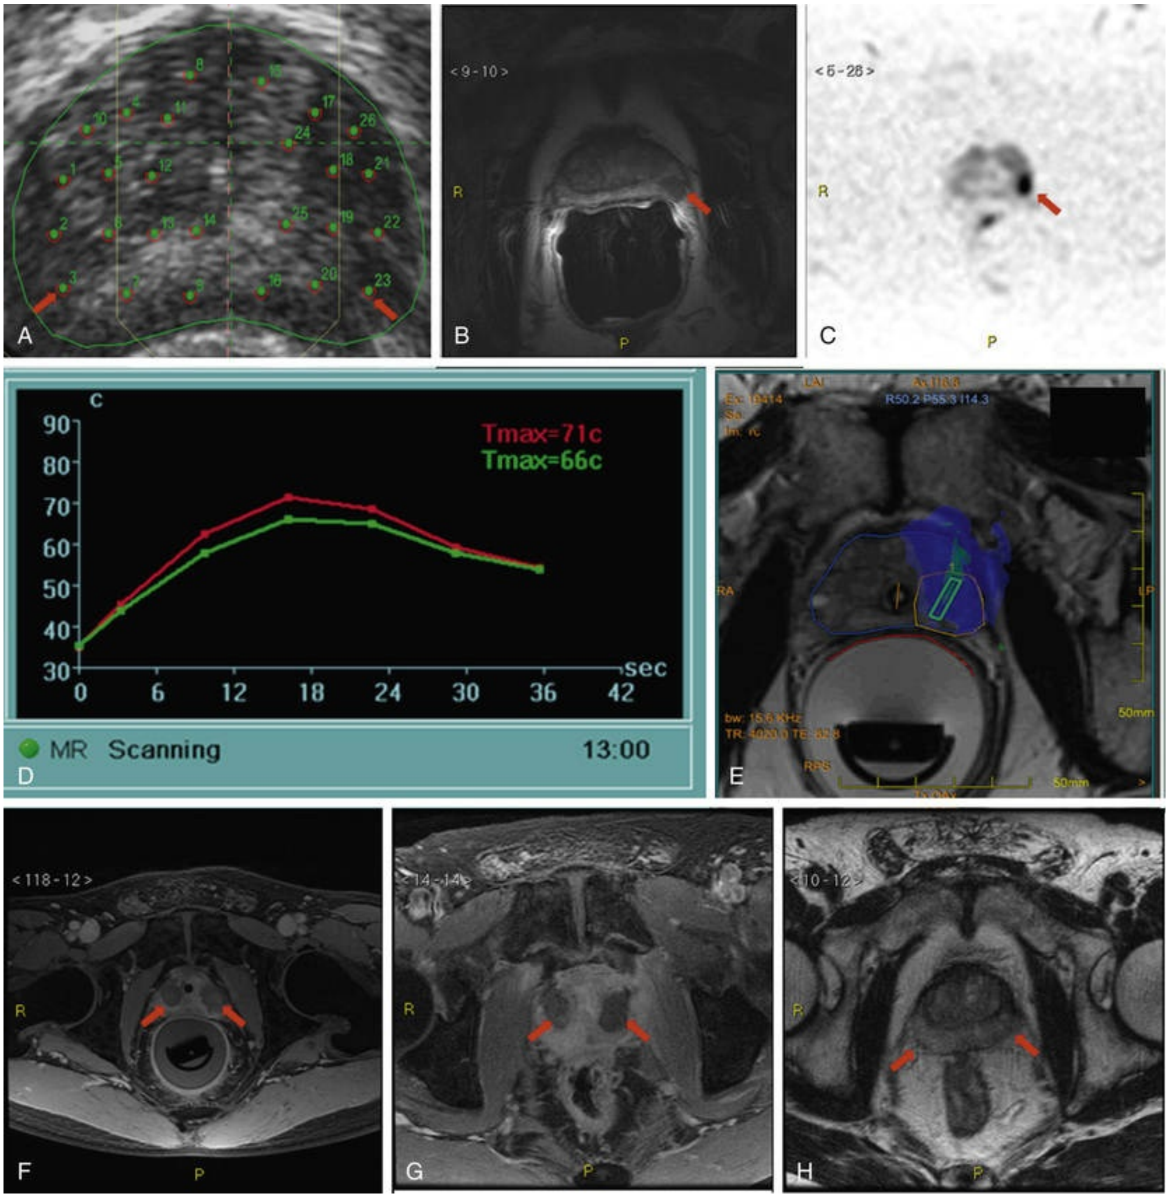

FIG. 158.5 54-year-old male patient with PSA 7.7 and biopsy-proven Gleason 3+3 prostate carcinoma. (A) Saturation biopsy map showing positions of 26 cores taken. Core 3 and 23 were positive for Gleason 3+3 prostate carcinoma *(arrows),* measuring 3 mm and 4 mm in the mid-cores, respectively. (B,C) Pretreatment axial T2-weighted fast spin-echo MR image (TR/TE, 3300/90) and corresponding axial DWI (TR/TE, 105/6000, *b* = 2000 mm/s^2) showing well-demarcated lesion in left posterior peripheral zone at mid-gland level corresponding to core 23 *(arrow).* It also shows suspicious type 3 curve on DCE MRI *(not shown).* The other lesion in the right posterior peripheral zone was not visualized. (D,E) Intraoperative MRgFUS image showing focused ultrasound beam path overlaid on treatment plan for left posterior peripheral zone lesion (E) with real-time thermal map (D). (F) Immediate post-treatment T1-weighted postcontrast MR image (TR/TE, 400/6) showing nonperfused devascularized ablated volumes in bilateral peripheral zones *(arrows).* (G) One-month post-

treatment T1-weighted postcontrast MR image (TR/TE, 400/6) showing persistence of nonperfused devascularized ablated volumes in bilateral peripheral zones *(arrows).* (H) Axial T2-weighted fast spin-echo MR image (TR/TE, 3300/90) on 2-year follow-up showing loss of volume with fibrosis in treated area *(arrow).* (From Tay KJ, Cheng CWS, Lau WKO, et al. Focal therapy for prostate cancer with in-bore MR-guided focused ultrasound: two-year follow-up of a phase I trial—complications and functional outcomes. *Radiology* 285(2):620–628, 2017.)

Another new development that has arisen as a result of miniaturization of HIFU probes is MRI-guided transurethral ultrasound ablation (TULSA) (Fig. 158.6) (Burtnyk et al., 2015). In-bore MRI guidance offers the advantages of thermometry and anatomic resolution, and via a transurethral approach, TULSA could potentially be much more efficiently applied to the anterior prostate. Chin et al. (2016) reported a multicenter phase I clinical trial of whole-gland TULSA showing the technology to be safe and technically precise, achieving spatial control of thermal ablation to be within 1.3 mm on MRI thermometry, no post-treatment changes in functional scores, and a 3.3% grade 3 complication rate with no grade 4/5 complications. Although further clinical experience is required with this modality, TULSA appears to be promising for application to focal therapy.

Magnetic resonance imaging-guided transurethral ultrasound ablation of prostate tissue in patients with localized prostate cancer: a prospective phase 1 clinical trial. *Eur Urol* 70(3):447–455, 2016.)

Laser

Focal laser ablation (FLA) refers to the creation of coagulative necrosis using an interstitially placed laser fiber. The ablation zone is guided by the laser fiber, and tissue destruction occurs only within a fixed distance from the fiber tip, offering the possibility of true focal ablation where accurate and predictable tissue destruction zones can theoretically be safe within close proximity to vital structures (Oto et al., 2013). The disadvantages are that longer procedure times or extra laser fibers may be necessary for ablation of larger lesions, and additional care may be needed to treat the lesion with an adequate margin. Histopathologic analysis of the ablation zone shows neovascularization and increased tumor mitotic activity at the edge, reinforcing the need for a safety margin during treatment (Fig. 158.7) (Bomers et al., 2017). The laser fiber can be placed transperineally or transrectally via a delivery trocar.

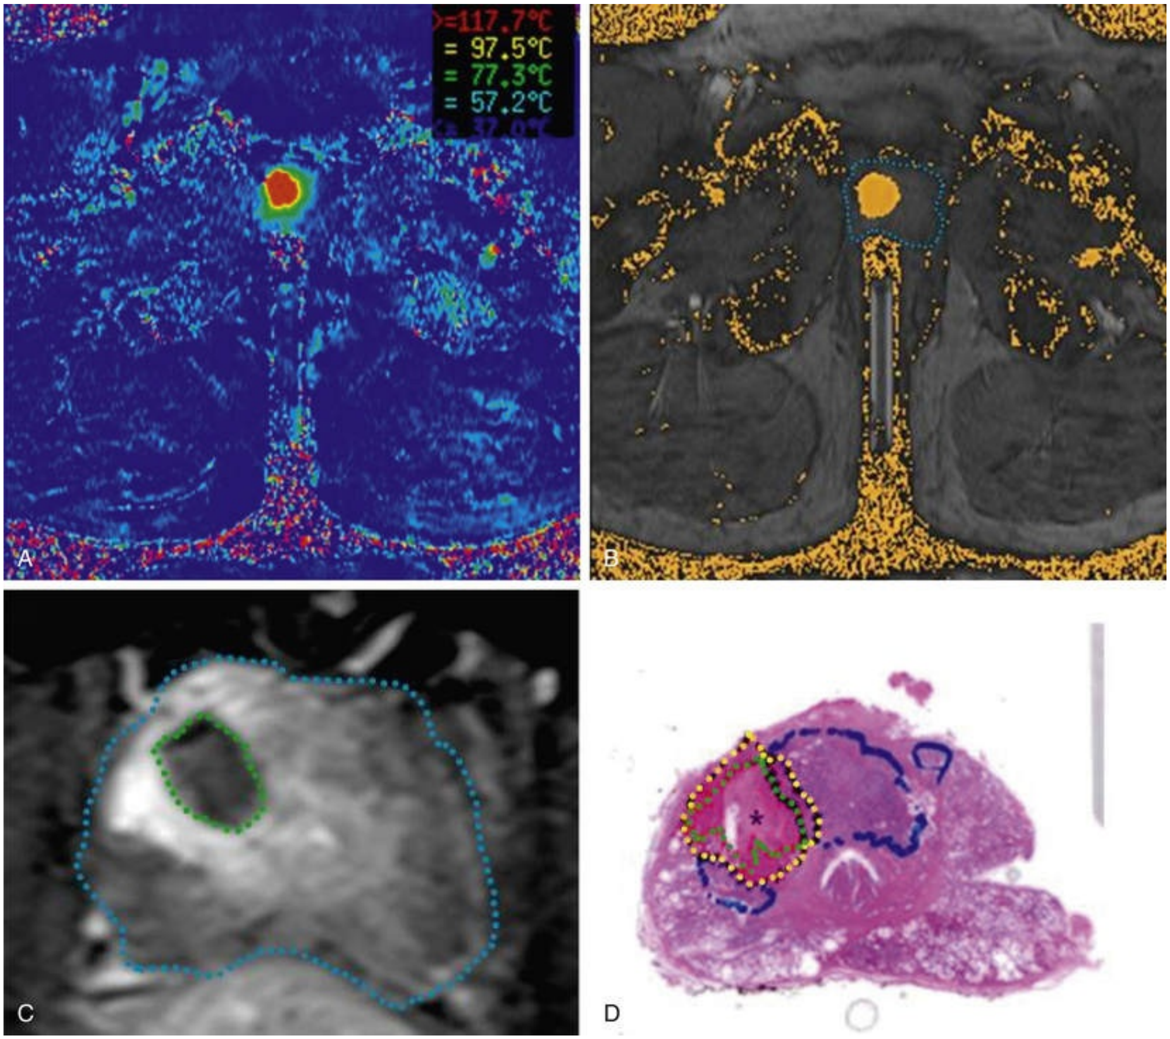

FIG. 158.7 Images of a 67-year-old male patient with a Gleason score of 3 + 4 = 7 in his right transition zone. (A) Real-time MRI-temperature map acquired during focal laser ablation. (B) Anatomical MRI of the prostate *(delineated in blue)* with the Arrhenius-based damage-estimation zone as *orange overlay.* (C) Postablation axial T1-weighted contrast-enhanced image. The prostate is delineated in *blue,* and the nonenhancing necrotic tissue is in green. (D) Whole-mount H&E stain of the prostate. The necrotic tissue is delineated in *green,* the perinecrotic tissue in *yellow,* and vital tumor in *blue.* (From Bomers JGR, Cornel EB, Futterer JJ, et al. MRI-guided focal laser ablation for prostate cancer followed by radical prostatectomy: correlation of treatment effects with imaging. *World J Urol* 35(5):703–711, 2017. Open Access via Creative Commons Attribution 4.0 International License: http://creativecommons.org/licenses/by/4.0/)

Reported outcomes regarding the utilization of FLA to date are very small series with short follow-up (Table 158.5). Eggener et al. (2016) treated 27 men in a phase II trial of in-bore MRI-guided FLA, reporting an 11% infield and 30% outfield positive biopsy rate at 12 months with no change in IIEF from baseline. The authors described the use of a 14-gauge titanium introducer with a polytetrafluoroethylene catheter placed in the target lesion followed by a 17-gauge laser applicator placed through each catheter (Fig. 158.8). Treatment duration was 60 to 120 seconds at 6 to 15 W based on the intended size of the ablative zone and repeated as needed. The target ablation temperature was a minimum of 60°C with ablation extending more than 5 mm beyond the lesion. Notably, 85% of this cohort comprised low-risk patients.

(From Eggener SE, Yousuf A, Watson S, et al. Phase II evaluation of magnetic resonance imaging guided focal laser ablation of prostate cancer. *J Urol* 196(6):1670–1675, 2016.)

Natarajan et al. (2017) reported on 10 men with mainly Gleason 7 cancer (80%) undergoing FLA under local anesthesia using a modified MRI-TRUS fusion biopsy device where a higher recurrence rate (40% infield and outfield for clinically significant cancer) was observed. They concluded that, although it is safe and efficient to perform FLA in a clinic setting, close attention should be paid to achieving an adequate treatment margin.

Irreversible Electroporation

IRE is a nonthermal ablative technique that uses short pulses of direct-current electricity to produce irreversible pores in the cell membrane, leading to cell death (Onik et al., 2007a). IRE preferentially damages cells while preserving connective tissue architecture that could theoretically serve as a scaffolding for new cells to grow. The ablation occurs between two or more probes, typically placed 10 to 20 mm apart (Fig. 158.9). Energy is usually delivered in two components, with the first 20 pulses delivered to characterize the electrical current dynamics between the probe pair. Once adjustments are finalized, the patient is placed in deep anesthesia to avoid muscle depolarization, and the final component of 70 pulses per probe pair is delivered to produce the final tissue ablation. The effective field strength to be achieved is higher than 1600 volts/cm between any given probe pair.

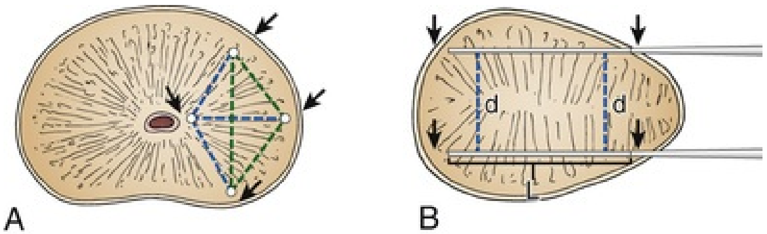

FIG. 158.9 Electrode metrics. (A) Axial representation of probe placement geometry using probe insertion initiated in periurethral position with additional probes configured radially *(blue dashed lines)* from this point. The closest distance from each probe to the capsule or urethra *(arrows)* was no more than 5 mm. The distance between probe pairs *(blue dashed lines)* used for ablation was between 10 and 20 mm. (B) Distances between probes *(d)* and length of needle exposure within tissues *(L)* are obtained to provide data for initial energy settings. Measurements were obtained to confirm parallel orientation *(d)* and 5 mm or greater distance tip to capsule *(arrows).* (From Murray KS, Ehdaie B, Musser J, et al. Pilot study to assess safety and clinical outcomes of irreversible electroporation for partial gland ablation in men with prostate cancer. *J Urol* 196(3):883–890, 2016.)

There are three early-phase studies with an aggregate of 104 men who have undergone focal IRE for prostate cancer (Murray et al., 2016; Valerio et al., 2017; van den Bos et al., 2018) (Table 158.6). One study reported the use of IRE with hemiablation or anterior zonal ablation (Murray et al., 2016), and the other two treated men with focal ablation using a template grid (Valerio et al., 2017; van den Bos et al., 2018). Overall, the procedure appears to be safe with no grade 4 to 5 complications reported. Urinary function appeared to be maintained well with almost all men remaining continent, though some reduction in erectile function scores were noted, withslightly fewer men having erections sufficient for sexual intercourse. Further evaluation with larger cohorts is necessary to determine whether the theoretical benefit of connective tissue preservation bears fruition. Indeed, in a 16-patient ablate and resect study, the majority of the men did have fibrinoid necrosis in the unilateral neurovascular bundle and denudation of the prostatic urethra (van den Bos et al., 2016b). In this study, the interval between ablation and resection was only 1 month, and whether the remaining connective tissue does allow later regrowth and functional recovery is unknown (Fig. 158.10).

TABLE 158.6

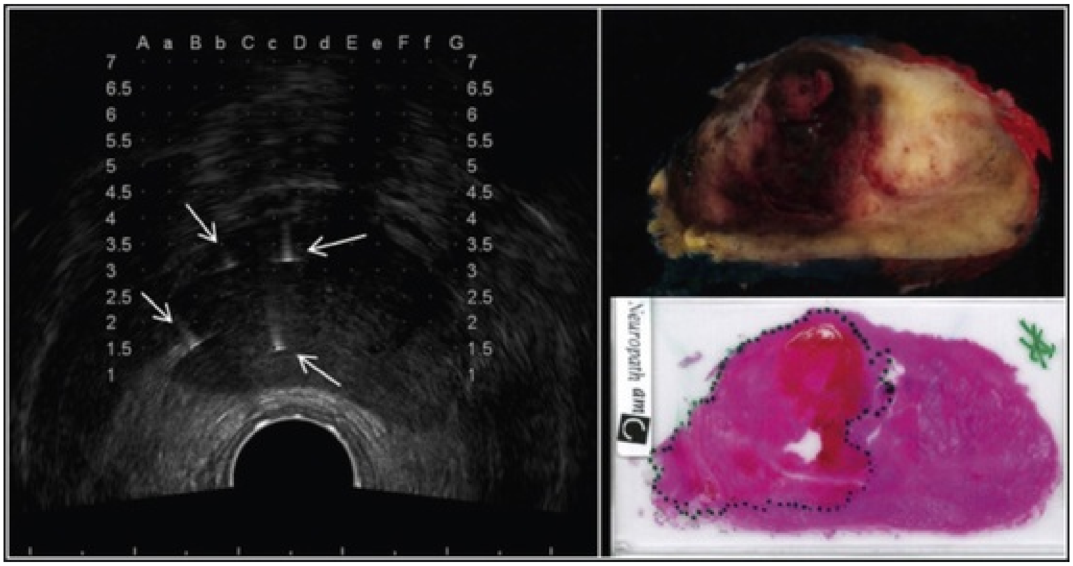

FIG. 158.10 Perioperative TRUS image with inserted irreversible electroporation electrode *(arrows),* with corresponding whole-mounted prostate section and H&E slide. (From van den Bos W, Jurhill RR, de Bruin DM, et al. Histopathological outcomes after irreversible electroporation for prostate cancer: results of an ablate and resect study. *J Urol* 196(2):552–559, 2016b.)

A significant infield positive biopsy rate, including that of clinically significant cancer, was noted in the two studies using focal ablation, but this was much less so in the study in which zonal ablation was deployed. This suggests that the treatment effect when IRE is performed in a focal manner warrants closer examination, and attention to the ablation margin is necessary when focal ablation is planned.

Although a head-to-head trial does not exist, Scheltema et al. (2018) analyzed 50 matched pairs of men who underwent focal IRE or robotic-assisted radical prostatectomy and found that IRE was significantly superior to robotic-assisted radical prostatectomy in preserving pad-free continence and erections sufficient for intercourse, though the focal IRE patients continued to experience cancer recurrence, with 13 men having residual significant prostate cancer and requiring salvage therapy.

Vascular-Targeted Photodynamic Therapy

In vascular-targeted photodynamic (VTP) therapy, low-power near-infrared laser light of specific wavelength destroys targeted tissues that have been photosensitized with an intravascular agent, preferentially taken up by tumor cells (Azzouzi et al., 2013). This occurs via the production of reactive oxygen species in the target zone, causing irreversible damage to cell membranes and small arterioles and leading to tumor necrosis (Vakrat-Haglili et al., 2005).

TOOKAD Soluble (WST11, padeliporfin; palladium bacteriopheophorbide monolysotaurine) is a photosensitizer of the bacteriochlorophyll derivatives family. Compared with predecessor agents, it is highly soluble, remains confined to the vasculature even at high doses, and is rapidly cleared by the renal and hepatic systems. Three phase II trials (Table 158.7) using the TOOKAD Soluble photosensitizer for focal VTP of men with Gleason 3+3 prostate cancer have shown the technology to be safe (Azzouzi et al., 2015). The authors describe a single intravenous administration of TOOKAD Soluble at 4 mg/kg followed by local illumination of the targeted zone using a 753-nm laser light at 150 mW/cm and 200 J/cm via a transperineally positioned laser fiber within the prostate. The total anesthesia time was 2 hours, and on completion the patients were required to wear protective eyewear and stay in low-level light for the following hour post-treatment. A combined analysis of the three trials showed an infield positive biopsy rate of 31.6% overall and 19.4% in those who underwent hemiablation.

TABLE 158.7

Summary of Published Focal Vascular-Targeted Photodynamic Series

AUTHOR	*N*	PREDIAGNOSTIC	DECLARED INCLUSION	FINAL	ABLATION

		WORKUP	CRITERIA	DEMOGRAPHIC	PLAN
Azzouzi et al., 2015	117[a]	mpMRI+ TMB	PSA <10 ng/mL Gleason pattern 4 allowed at low volume (<3 cores, ≤3 mm max cancer core length)	Gleason 3+3 – 116 (99.1%)	Hemi-ablation (Abdollah et al., 2011) and subtotal ablation (Djavan et al., 1999)

[a] This was a combined analysis of three phase II trials.

BCR, biochemical recurrence; *BPFS,* biochemical progression–free survival; *DRE,* digital rectal examination; *IIEF,* international index for erectile function; *mpMRI,* multiparametric magnetic resonance imaging; NR, not reported; *NA,* not applicable; *PSA,* prostate-specific antigen; *TRUS,* transrectal ultrasonography; *TMB,* transperineal mapping biopsy.

Azzouzi et al. (2017) randomized 415 men with low-risk prostate cancer to focal VTP or active surveillance and demonstrated that focal therapy significantly improved negative biopsy at 2 years and decreased disease progression and the requirement for definitive disease intervention. Of the 216 men assigned to VTP, 196 received the treatment and 195 completed 24 months of follow-up. In the active surveillance arm, 174 men completed 24 months of follow-up. Overall, cancer progression rate (volume, grade, or PSA progression) in the active surveillance arm was 58% compared with 28% in the VTP arm. This is the first randomized trial with level 1 evidence comparing focal therapy to an accepted management strategy demonstrating a meaningful clinical benefit. The study limitations include a Gleason 6 cohort, short follow-up, use of surrogate end points that do not necessarily reflect overall/disease-specific survival, and the fact that the outcome measure may represent reclassification rather than true progression.

Brachytherapy

Treatment simulation studies show that an adequate dose delivery to perform focal therapy can be achieved with brachytherapy (Butler and Merrick, 2016;

Haworth et al., 2016). The benefit of brachytherapy is the sharp falloff in radiation dose within a few millimeters of the radiation source. The radiation dose can be further conformed to the desired treatment area by modulating the rate of radioisotope flow through the interstitial catheters when high-dose-rate (HDR) brachytherapy is performed. With seed or low-dose-rate (LDR) brachytherapy, reported urinary toxicity rates are low, and seem dependent on pretreatment symptoms and urethral dose (Gutman et al., 2006). On the other hand, high-dose-rate (HDR) brachytherapy can be associated with a urethral stricture rate as high as 8.2% within the first 2 years of treatment (Hindson et al., 2013). These typically occur at the level of the prostatic apex or bulbous urethra. Studies involving the use of radiation for focal ablation of prostate cancer are ongoing.

Other Modalities

Technical advances in external beam radiation have made it possible to deliver a highly focused dose within the prostate, sparing vital structures (Vainshtein et al., 2012). Dosimetric feasibility has been demonstrated in the use of stereotactic body radiotherapy for focal therapy though there has not been any clinical trial (Kishan et al., 2015).

Another promising modality is the photothermal excitation of nanoshells. These preferentially accumulate in fenestrated perivascular spaces of tumors, causing the preferential death of cancer cells (Stern et al., 2016). An open-label multicenter trial treating men with low- to intermediate-risk prostate cancer is now under way (NCT02680535).

PRX302 is a genetically modified pore-forming protein (aerolysin) that is activated by enzymatically active PSA within the prostate, subsequently causing cell death. A pilot study of 18 patients showed that a single MR-fusion transperineal administration of PRX302 was well tolerated, with two patients having complete and seven partial histologic responses (Shanmugabavan et al., 2017).

NanoPac, sterilized nanoparticles of paclitaxel, is another modality being studied in the phase IIa setting as an intratumoral injectable agent (NCT03077659). More devices and pharmaceuticals are expected to be trialed in the field of FT.

Adjuvants to Focal Therapy

Many of the proponents of FT believe that a successful treatment will ultimately hinge not on a device alone but rather on a combinatorial approach (Baust et al., 2015, 2018). Stereotactic Body Radiation Therapy (SBRT) strategies routinely utilize a boost directed to the tumor focus within the prostate, with only 5-10 external beam fractions required. A pilot study of 50 patients undergoing SBRT with a boost to the MR-visible tumor showed no biochemical recurrence at 2-year follow-up and an acute GU/GI toxicity rate of 8%/2% and late toxicity rate of 6%/0% (grade 3) (Aluwini et al., 2013). The added efficacy of combining a nonradiation focal ablative therapy with low dose/fraction external beam irradiation is yet to be determined. In another investigative approach, DOTA-AR, a bombesin-antagonist peptide targeting Gastrin-related Peptide receptor (GRPr), when conjugated to a radioisotope has been found to cause tumor growth delay when used in combination with WST11 (TOOKAD® Soluble) in GRPr-positive prostate cancer xenographs (Kim et al., 2017).

In focal cryotherapy, there has been early research exploring means to enhance cell kill. The use of androgen deprivation in combination with cryoablation has not been deemed useful to increase cell kill (Grossgold et al., 2014). Alteration of the extracellular environment by infusing a solution with a higher than physiologic eutectic temperature can enhance cryoablation by promoting extra- and intra-cellular eutectic ice formation to provide a cell-kill mechanism in addition to intracellular lethal ice (Han and Bischof, 2004). Several studies have shown the benefits of chemotherapeutic agents (e.g., 5-fluoruracil, cisplatin, doxorubicin, mitomycin and bleomycin, vinorelbine, navelbine and tumor necrosis factor [TNF]-related apoptosis-inducing ligand) as apoptosis inducers to enhance cell destruction at milder temperatures in vitro (Baust et al., 2015). TNF-alpha, a proinflammatory cytokine, is also being explored as an enhancer to cryoablation (Jiang et al., 2008). Vitamin D3 has been found to improve the apoptotic effects of cryoablation at sublethal isotherms in murine models (Santucci et al., 2011).

At present, there is no widely applicable and ubiquitous substance that can be utilized to augment device-mediated cell kill but further research in this area will likely yield further refinements to techniques in prostate focal therapy.

Post–Focal Therapy Follow-Up

With focal therapy, traditional markers of therapeutic success may be less relevant. After curative radical prostatectomy, PSA is expected to be undetectable, and after radiation therapy, a significant rise is needed to define biochemical recurrence. After focal therapy, however, the expected fall in PSA has been variable, with some studies reporting a 50% to 80% reduction. The PSA level would depend on the amount of residual prostate epithelium that may continue to grow and is thus less informative as an absolute marker.

Similarly, clinical examination of the prostate may be affected by post-treatment scarring and contraction of the original tumor site, making follow-up biopsy less reliable. These post-treatment findings are seen on mpMRI, TRUS, and contrast-enhanced ultrasonography (CEUS), with increasing ablation zone volume in the early post-treatment period followed by a gradual overall reduction in prostate volume caused by ablation zone fibrosis and deformation (Scheltema et al., 2017).

Compared with traditional treatments, there are additional dimensions to cancer recurrence after focal therapy that affect downstream management of these patients. In a 2015 Joint International Consultation on Urological Diseases (ICUD)/Society Internationale de Urologie (SIU) project on image-guided focal therapy, success was defined as the following (Polascik & Amin, 2015):

1. Within the treated or infield area as the:
    a. eradication of the tumor focus in the short term.
    b. absence of clinically significant cancer in the intermediate to long-term.
2. Within the untreated or outfield area for the development of clinically significant cancer. In the short term, this outfield cancer focus likely represents selection failure, and in the intermediate- to long-term, this may represent de novo cancer.

This consultation recommended an mpMRI with mandatory targeted biopsy of 4 to 6 cores in the treated area at 3 to 6 months, then mpMRI at 1 to 2 years and 5 years with targeted biopsy as needed, especially if a new lesion should become manifest. A systematic biopsy was also recommended at 1 to 2 years and 5 years to provide further histologic evaluation of the untreated zone for potential outfield recurrence.

It should be noted that there is limited experience with mpMRI in the post–focal treatment arena, and it is unknown how post-treatment changes interact with mpMRI performance. In one whole-gland HIFU series, the sensitivity and specificity of DCE-MRI were reported to be 73% to 87% and 73% to 82%, respectively (Punwani et al., 2012). As radiologic experience in the post–focal therapy prostate accrues, there will be much to for practitioners to learn, especially in those patients experiencing treatment failure.

Because of the intensity of follow-up, investigators have also sought alternative imaging modalities to mitigate the cost of mpMRI and the morbidity of repeated biopsies. One group analyzed 16 men in a pilot study of focal IRE before radical prostatectomy and found that CEUS was as good as mpMRI in determining early ablation success, whereas TRUS was not able to visualize the ablation zone post-treatment (van den Bos et al., 2016a). This is an important area for further research.

Conclusions and Areas for Future Research

“Is cure possible when necessary and necessary when possible?”

—Willet Whitmore

Better health care leading to longer life expectancy, an increasing awareness of prostate cancer, and widespread use of PSA screening have led to more prostate cancers being diagnosed. Meanwhile, advances in imaging and biopsy have resulted in these cancers being diagnosed at an earlier stage when, in a subset of patients, focal therapy may render the cancer cured, or at least controlled for a significant duration. Because the biology of prostate cancer for the most part is one of a slowly growing disease, the management of prostate cancer has the potential to convert this from an acute to a chronic disease. Focal therapy, with its combination of eradicating clinically significant cancer while monitoring uninvolved parenchyma on an active surveillance protocol, has the ability to avoid overtreatment and preserve genitourinary function for many years. Many men today equally value quality of life as much as cancer control, and image-guided ablation is well positioned to achieve both functional metrics and cancer control. However, the journey remains filled with challenges, and focal therapy remains a work in progress with significant room for further research (Tay et al., 2017b).

First, it remains unknown whether satellite, insignificant cancers can remain safely untreated. Present efforts have focused on identifying the index lesion, or the lesion with the highest stage/grade, within the prostate for ablation. However, cancers that are small or insignificant at the time of treatment may progress to a more aggressive phenotype. Indeed, the only randomized trial of prostate focal therapy compared with active surveillance found a progression-free survival benefit in men with low-risk prostate cancer, suggesting that there is some value to treating lower-grade lesions (Azzouzi et al., 2017). Further research is needed to develop clinical, imaging, and genetic biomarkers that can help to profile all the truly aggressive lesions within the prostate. Techniques focusing on functional and metabolic imaging, in addition to anatomic imaging, may be an area where such profiling can converge such that genetic and metabolic markers can be detected by imaging for highly accurate and appropriate image-guided ablation. In the meantime, continued close surveillance of any small, insignificant lesions remains necessary.

Second, the long-term cost-effectiveness of focal therapy remains unknown. Up to one-half of men on active surveillance for prostate cancer eventually undergo radical intervention (Hamdy et al., 2016; Klotz et al., 2015). By restricting treatment to the clinically significant lesion and placing the remainder of the gland on surveillance, we expect to observe that a substantial of proportion of men *will* progress and require either additional focal ablation or radical intervention. This might be viewed as the cost for using focal therapy as an extender of active surveillance to preserve quality of life, but patients will have to be prepared to undergo repeated treatments. In the long term, the cost and morbidity of surveillance and repeated focal therapy are not known. Additionally, the morbidity of radical intervention after repeated focal therapy is unknown. The incremental cost-effectiveness of the entire focal therapy strategy remains to be defined.

Third, focal therapy may have to be further optimized using adjuvants to obtain lasting oncologic control. Excellent outcomes with wide excision as compared with mastectomy for breast cancer have often been cited as the model for successful prostate focal therapy. However, although wide excision in breast cancer is routinely paired with adjuvant radiotherapy, there have been no trials exploring adjuvants such as whole-gland irradiation in conjunction with focal ablation in prostate cancer. There are several promising adjuvants in early development, and the downstream challenge is to demonstrate clinical safety and efficacy of such adjuncts in human trials.

Key Points

- The biologic basis of focal therapy is predicated on the index lesion being the dominant tumor focus in the prostate that drives cancer progression and metastasis. Although the majority of prostate cancers are multifocal, most of the time, secondary cancers (cancers other than the index lesion) tend to be small, low grade and of low clinical significance. Hence, if the index lesion could be completely ablated, men could potentially be cured of cancer or have their low-grade cancer monitored with active surveillance.

- A successful focal therapy strategy depends on a multidisciplinary team to accurately determine the disease extent/location through advanced imaging and biopsy, ascertain that the patient will be compliant to follow-up, completely ablate the index lesion(s), and monitor the patient post-treatment with a view to future targeted treatment of either persistent or de novo disease, or conversion to whole-gland treatment as necessary.
- mpMRI has become a key enabler for prostate focal therapy because of its ability to preferentially detect high-grade lesions, improve the detection of anterior-zone cancers, improve the detection of EPE, and accurately identify the index lesions for targeted biopsy. However, systematic biopsy remains necessary to evaluate the prostate gland before focal therapy because of the 10% to 15% miss rate with mpMRI. Other imaging modalities such as multiparametric ultrasonography, or PSMA-PET CT/MRI have potential use in this area but remain to be further evaluated.
- Focal therapy can be applied in various patterns (hemiablation, quadrant ablation, lesion ablation) using different technologies (e.g., cryotherapy, HIFU, IRE, laser). The chosen approach depends on the location of the tumor, the desired ablative technology that is available, and other anatomic considerations that may be peculiar to the patient.
- After prostate focal therapy, PSA, which is a traditional marker of therapeutic success, is less relevant because its levels are affected by the amount of residual prostate epithelium that may continue to grow. MRI and prostate biopsies are recommended to assess the treated (infield) area and the untreated (outfield) area.
- Future research endeavors should focus on better patient selection using clinical, imaging, and/or genetic biomarkers, cost-effectiveness studies, and the investigation of adjuvant agents to improve the efficacy of focal therapy in prostate cancer.

Treatment of Locally Advanced Prostate Cancer

Maxwell V. Meng MD, Peter R. Carroll MD, MPH

The widespread application of prostate cancer early-detection efforts in the United States has resulted in both an increased number of prostate cancers diagnosed and the earlier identification of these tumors. Despite the stage migration associated with prostate-specific antigen (PSA) testing and the growing number of low-stage and organ-confined tumors, at least 10% of men with newly diagnosed prostate cancer have locally advanced disease (T3NX/+M0). Although this proportion has declined somewhat, it remains significant and has been relatively constant during the past decade. Those men with locally advanced or metastatic prostate cancer at the time of presentation contribute disproportionately to prostate cancer mortality, and improved treatments for such men could have a significant positive impact on overall morbidity and mortality caused by this disease.

Currently, no consensus exists regarding the optimal management of locally advanced prostate cancer. Unlike with clinically localized and low-grade prostate cancer, for which comparable and excellent outcomes may be achieved with a variety of interventions, treatment of disease with local or regional spread by any single modality is associated with significant risk for recurrent disease. Ongoing interest in, and the development and evaluation of, combination therapy, as well as improvements in risk assessment, should improve cancer outcomes while minimizing treatment-related morbidity and adverse impact on quality of life in these patients. Three analyses suggest that men with higher-risk disease characteristics may have reductions in disease-specific mortality and metastatic progression after radical prostatectomy compared with other treatment modalities (Cooperberg et al., 2010; Sooriakumaran et al., 2016; Zelefsky et al., 2010).

Definition

Traditionally, the identification of patients with locally advanced disease was based on clinical examination (e.g., digital rectal examination) and clear evidence of spread outside of the prostate capsule (clinical stage T3a), involvement of the seminal vesicles (cT3b), or involvement of adjacent organs (cT4) (Greene et al., 2002). However, the contemporary use of PSA testing has led to the majority of men diagnosed with prostate cancer initially having nonpalpable cancers (cT1c). **Features other than clinical T stage most often contribute to the identification of men with advanced disease and a concomitant increased risk for failure after primary therapy.** Thus improved methods of risk assessment have facilitated categorization of men as “high risk” and involve consideration of variables such as serum PSA level and Gleason score in addition to clinical stage. The subsequent discussion focuses on this broader definition of locally advanced disease, with inclusion of those patients with regional or lymph node involvement without distant metastasis (T3–4N ±M0).

Contemporary Risk Assessment

Multiple methods are currently available to accurately risk stratify men with prostate cancer (D'Amico et al., 1999; Partin et al., 1997; Shariat et al., 2008; Tewari et al., 2001). The Partin tables were initially constructed in the 1990s and updated in 2001, 2013, and 2017, assisting in the preoperative prediction of final pathologic stage in men with clinically localized prostate cancer undergoing radical prostatectomy (Eifler et al., 2013; Partin et al., 2001). Although clinical stage, serum PSA level, and Gleason score individually predict pathologic stage and prognosis, the combination of these three variables increases the accuracy of this assessment. These data continue to illustrate that a significant number of men thought to harbor organ-confined tumors have more advanced disease. The ability to assess pathologic stage permits better pretreatment counseling of patients and more appropriate selection of therapy, and consideration of those with more advanced disease for novel clinical trials. **The most important pathologic criteria predicting prognosis after radical prostatectomy are Gleason score, surgical margin status, and presence of non–organ-confined disease (e.g., extracapsular extension, seminal vesicle invasion, lymph node**

involvement).

In addition, to help predict pathologic stage, biopsy information has been incorporated into models estimating cancer outcomes, primarily PSA- or biochemical disease-free survival (BDFS), after treatment. Whereas BDFS is a frequent end point of current prostate cancer studies, it merely represents an intermediate surrogate outcome variable; further trials and studies are necessary to confirm the utility of biochemical recurrence as a marker for reduced prostate cancer–specific survival after treatment. The most widely used tools to predict disease recurrence after local therapy are the nomograms developed by Kattan et al. (1998, 2000). In all pretreatment nomograms, clinical stage, biopsy Gleason grade, and pretreatment serum PSA level are incorporated to predict the continuous risk for disease progression after definitive local therapy; models for radiation therapy (RT) also include data on use of androgen deprivation (AD), total radiation dose, and combination treatment (i.e., external-beam and permanent brachytherapy). The radical prostatectomy nomogram was based on nearly 1000 patients with clinically localized disease (T1c–T3aNXM0); thus this model is not applicable for those men with evidence of seminal vesicle involvement or regional spread.

Key Points: Risk Assessment

- Risk assessment is best performed by a combination of serum PSA level, T stage, cancer grade, and extent of cancer on biopsy.
- Imaging plays a limited role in identifying most patients with high-risk features for whom local therapy may fail.

To simplify risk stratification, men with prostate cancer can be grouped into fewer categories but with maintenance of the ability to predict disease behavior and response to intervention. D'Amico et al. (1998) defined patients at low, intermediate, and high risk for biochemical failure, still based on pretreatment disease characteristics (clinical stage, PSA value, Gleason score). Recurrence after treatment may be caused by unrecognized micrometastatic disease or persistence of locoregional disease. Other variations of simplified risk stratification have been developed and validated, with inclusion of features such as ethnicity and pathologic findings (Cooperberg et al., 2005; Moul et al., 2001). The Cancer of the Prostate Risk Assessment (CAPRA) score, ranging from 0 to

10, provides another method to assess risk, with each 2-point increase in score doubling the risk for recurrence after prostatectomy. It is easily calculated from PSA, T stage, patient age, cancer grade and volume; has been validated in several populations; and also predicts disease-specific and overall mortality (Cooperberg et al., 2009). **Although men with "low-risk" disease generally do well and are unlikely to have biochemical recurrence, men in the intermediate- and high-risk groups may have widely discrepant outcomes. Therefore men in these groups benefit from more modern and accurate risk prediction models and nomograms** (Mitchell et al., 2005).

Imaging Modalities

Although observations on traditional gray-scale ultrasonography can identify extraprostatic disease, the general ability to improve cancer staging is limited (Figs. 159.1 and 159.2). Directed biopsy of the seminal vesicles or prostate capsule can be obtained to confirm cT3 disease. Smith et al. (1997) found that transrectal ultrasonography did not improve the ability to stage prostate cancer; the area under the curve was .69 and .74 for transrectal ultrasonography in predicting extracapsular extension and seminal vesicle invasion, respectively, compared with .72 and .69 for digital rectal examination, respectively. Salo et al. (1987) reported high sensitivity (86%), specificity (94%), positive predictive value (92%), and negative predictive value (89%) of ultrasonography in predicting extracapsular extension in patients undergoing radical prostatectomy. However, more contemporary studies suggest otherwise, with lower sensitivities (23% to 66%), specificities (46% to 86%), positive predictive values (50% to 62%), and negative predictive values (49% to 69%). The inaccuracy of ultrasound staging for prostate cancer is likely a result of significant interobserver variability, often subtle signs of extraprostatic spread, and lower-volume tumors currently diagnosed. In general, transrectal ultrasonography understages rather than overstages prostate cancer. Newer ultrasound techniques such as color and power Doppler studies are under investigation to determine if observations of abnormal blood flow can increase the ability to detect and stage prostate tumors.

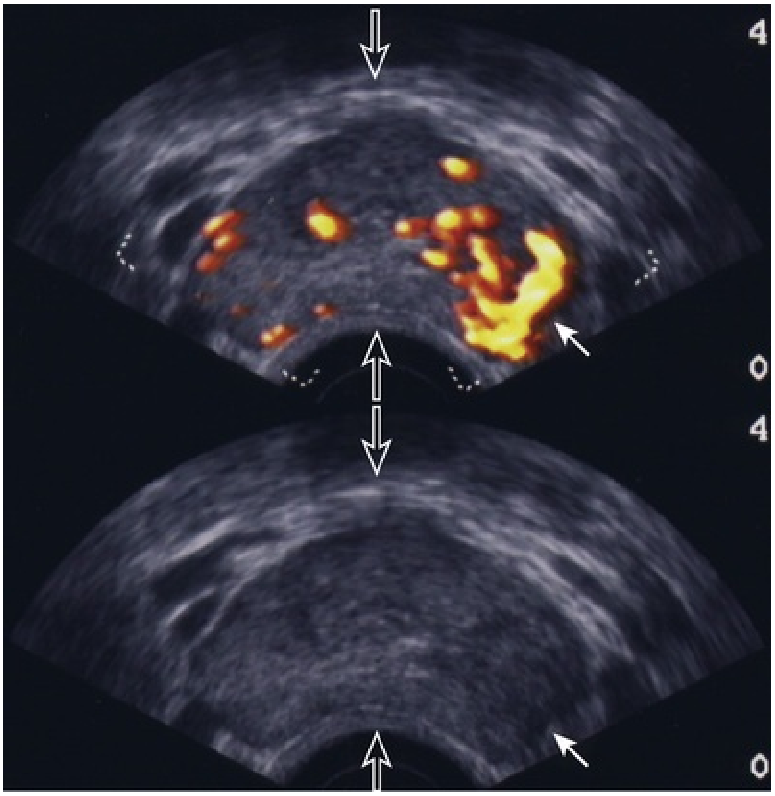

FIG. 159.1 Transrectal ultrasound examination demonstrates increased flow on color Doppler study at the left posterior *(upper panel, arrow)* with corresponding hypoechoic area on gray-scale images *(lower panel, arrow)*. Note the left lateral distortion and squaring of the capsule, suggesting extracapsular extension. (Courtesy of Dr. Katsuto Shinohara.)

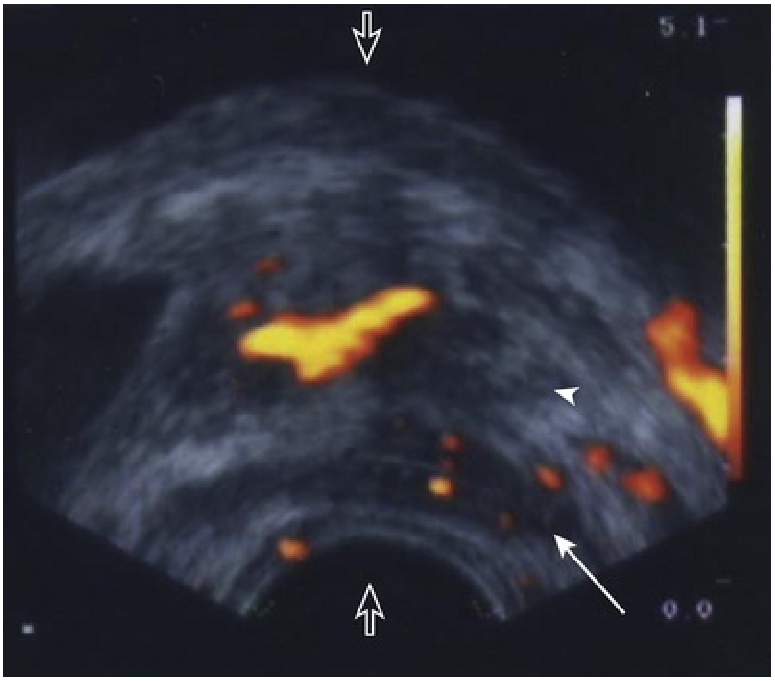

FIG. 159.2 Transrectal ultrasound examination demonstrates hypoechoic tumor in the left base *(arrowhead)* with likely extension into the ipsilateral seminal vesicle *(arrow)*. (Courtesy of Dr. Katsuto Shinohara.)

Endorectal magnetic resonance imaging (MRI) uses a magnetic coil placed in the rectum to achieve better visualization of the zonal anatomy of the prostate and may delineate subtle distinctions between T2a/b disease and T3 disease (Fig. 159.3). However, use of multiparametric MRI alone or in combination with magnetic resonance spectroscopy for tumor staging remains controversial, as is the necessity of the endorectal coil (Fulgham et al., 2017). Variable sensitivities (13% to 91%) and specificities (49% to 97%) have been reported for predicting extracapsular extension, in part attributed to variability in interpreting MRI and lack of uniform diagnostic criteria, and the revised structured reporting scheme of PI-RADS v2 should be adopted. Sauer et al. (2018) evaluated the accuracy of neurovascular bundle infiltration using multiparametric MRI at 3T and PI-RADS v2 in 198 men undergoing prostatectomy. Sensitivity and specificity of T staging were 64% and 89%, respectively, and the positive and negative predictive value of bundle infiltration were 80% and 92%, respectively. However, PI-RADS v2 score in the area adjacent to the neurovascular bundle had poor specificity (39%) and may not aid in determining eligibility for nerve preservation. In a cohort of 336 men with more than three cores involved with cancer, abnormal findings on digital rectal examination, and PSA level higher than 10 ng/mL undergoing radical prostatectomy, the specificity of MRI in predicting pT3 disease was 95%

(Cornud et al., 2002). Thus the use of MRI may be best limited to those patients with higher-risk features.

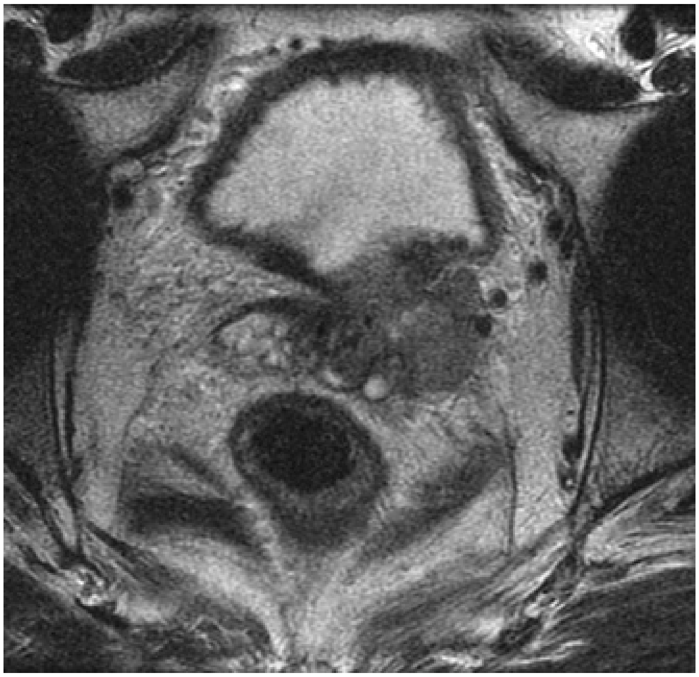

FIG. 159.3 Axial T2-weighted magnetic resonance image shows tumor involving the seminal vesicle and bladder base and extending into the adjacent fat.

Newer molecular imaging agents may gain a role in helping differentiate localized or locally advanced disease from regional and metastatic cancer. Although several radiotracers are approved by the Food and Drug Administration for PET imaging, most have focused on biochemical recurrence after definitive therapy (e.g., ^{18}F-fluciclovine) or improved detection of bony disease (e.g., ^{18}F-NaF). Prostate-specific membrane antigen (PSMA) targeting may have utility in identifying oligometastatic disease in high-risk disease by improving detection of limited lymph node involvement (Fig. 159.4). ^{68}Ga-PSMA-11 detected lymph nodes with 66% sensitivity and 99% specificity in men with intermediate- or high-risk disease undergoing prostatectomy (Maurer et al., 2016; van Leeuwen et al., 2017).

Novel Markers

It is clear that traditional clinical and pathologic parameters are limited in their ability to accurately predict local extent of tumor before treatment. Given the importance of assessing true pathologic stage, novel markers of advanced disease are necessary. Chu et al. (2003) used comparative genomic hybridization in primary prostate specimens and identified chromosomal regions potentially useful in discriminating between organ-confined and locally advanced tumors (Table 159.1). Prediction of stage by a model incorporating six aberrations in a stepwise fashion was accurate in 91.1% of cases. Further metabolic, genetic, and proteomic signatures will likely better define and discriminate between organ-confined and non–organ-confined prostate cancer (Ashida et al., 2004; Mehra et al., 2007; Paris et al., 2004; Sreekumar et al., 2009). Chromosomal rearrangements involving the androgen-regulated gene *TMPRSS2* and the *ETS* family genes are associated with higher pathologic stage, whereas the glycine metabolite sarcosine was more often elevated in metabolomic profiles of men with metastatic prostate cancer.

Preliminary genomic and transcriptome profiling of high-risk, clinically localized cases from men enrolled in CALGB 90203, which compared the outcomes of surgery alone versus neoadjuvant docetaxel and AD, confirms frequent alterations in *TMPRSS2-ERG* fusion, *TP53*, *PTEN*, *FOXA1*, and *SPOP*, but without *AR* amplification or mutations (Beltran et al., 2017). Linch et al. (2017) reported similar findings and also observed extensive genomic and inflammatory infiltrate heterogeneity and a correlation between Wnt signaling and immune suppression.

Several genomic biomarkers (Decipher, Oncotype DX, Prolaris) are now commercially available and variably applied in clinical practice to improve risk stratification compared with the use of clinical criteria alone. Spratt et al. (2018) developed and validated a novel clinical-genomic risk grouping system, which combined standard clinicopathologic variables with genomic results from the 22-gene Decipher test. Both 3- and 6-tier clinical-genomic risk groups outperformed traditional systems such as NCCN risk grouping and CAPRA score for prediction of metastasis and disease-specific survival. Moreover, 66.6% of patients classified by the NCCN 6-tier system would be reclassified using their novel 6-tier clinical-genomic risk groups. Similar application of genomics in men with adverse pathologic features at radical prostatectomy helps identify those at higher risk for disease-specific mortality and may guide decision making regarding adjuvant treatments (Karnes et al., 2018).

Trends in Incidence and Treatment

Within the Cancer of the Prostate Strategic Urological Research Endeavor (CaPSURE), Cooperberg et al. (2003) observed **a significant decrease in the fraction of men presenting with high-risk disease characteristics, as defined by D'Amico criteria, from 40.9% in 1989 to 1990 to 14.8% in 2001 to 2002.** However, alterations in cancer screening and use of PSA screening are likely to account for this reduction, with significantly fewer men presenting with elevations in PSA level higher than 20 ng/mL (32.8% to 7.2%); indeed, currently, higher Gleason grade defines a larger number of high-risk patients (61.5%). Overall, **the presence of clinically advanced disease (i.e., T3-4) decreased from 11.8% to 3.5%, with a decline from 32.3% to 21.9% in the high-risk group during the observation period.** Similar findings were reported from Johns Hopkins, with 69% of men classified as high risk solely by Gleason score in the contemporary cohort (2001 to 2010) compared with 29% in the earlier cohort (1992 to 2000) (Pierorazio et al., 2012). Outcomes over time, however, were comparable with respect to PSA outcomes and metastasis-free and disease-specific survival.

In men undergoing radical prostatectomy, the number with clinical evidence of locally advanced disease as defined by clinical stage (T3) has declined from 25.3% in 1987 to 2.8% in 2001 (Ward and Zincke, 2003). Although the use of PSA screening can account for part of this change, the more selective application of surgery and improved techniques of RT may also explain the decline in patients with cT3 disease undergoing prostatectomy. Within reports of men undergoing radical prostatectomy, the fraction of men with pT3 disease has decreased; these are highly selected patients with largely clinically localized disease at the time of treatment (Table 159.2). Roehl et al. (2004) reported that pathologically advanced disease decreased from 39% (1983 to 1991) to 31% (1992 to 2003). In men undergoing radical prostatectomy alone at the Cleveland Clinic, the overall rate of extracapsular extension decreased from 65.8% (1987 to 1989) to 25.2% (2000 to 2001), and this trend was true for all clinical tumor stages (T1c–T2b/c) and for pretreatment variables (PSA value, Gleason score).

Key Points: Trends in Incidence and Treatment

- Fewer men are presenting with locally advanced prostate cancer.
- There has been an increase in organ-confined cancers identified after radical prostatectomy.
- There was an increasing use of treatment modalities other than surgery for high-risk prostate cancers, yet this has evolved in recent years.

The National Comprehensive Cancer Network (NCCN) provided updated decision trees for men with prostate cancer to aid in treatment selection (NCCN, 2014, 2017). High risk for recurrence includes men with clinically advanced disease, both cT3a and cT3b–T4. Bone scans are indicated in these men and in those with T1 and PSA level greater than 20 ng/mL, or T2 and PSA level greater than 10 ng/mL, or Gleason score 8 or higher; pelvic computed tomography or MRI is also indicated for cT3–T4 disease or if the calculated probability of lymph node involvement is greater than 10%. In general, radical prostatectomy with extended pelvic lymphadenectomy is reserved for those high-risk men with low-volume tumors that can be completely excised. The alternative treatment strategy for these men with locally advanced disease and higher risk for biochemical failure is AD therapy combined with RT. The shift in treatment is also reflected within the CaPSURE database (Meng et al., 2005). A total of 6074 men with prostate cancer (clinical stage lower than T3aN0M0) were stratified according to risk group, of whom 26% were high risk. Fewer men in this group underwent radical prostatectomy compared with the low-risk cohort, with older age, advanced disease, and increased number of comorbidities significant predictors of treatment (external-beam RT or AD therapy) in multivariate modeling. In addition, more than half of high-risk men receiving RT also received AD, significantly more than in the low- and intermediate-risk groups ($P < .0001$). Data from the Surveillance, Epidemiology, and End Results (SEER) cancer registry between 1998 and 2005 show that nearly one-half of men with cT3–4M0 prostate cancer received a combination of AD and RT, while the rate of prostatectomy increased but was only 10% in 2005 (Lowrance et al., 2012). These trends, however, continue to evolve, and a recent report from CaPSURE has shown a significant increase in surgery for men with CAPRA score 6 to 10 (Fig. 159.5) (Cooperberg and Carroll, 2015).

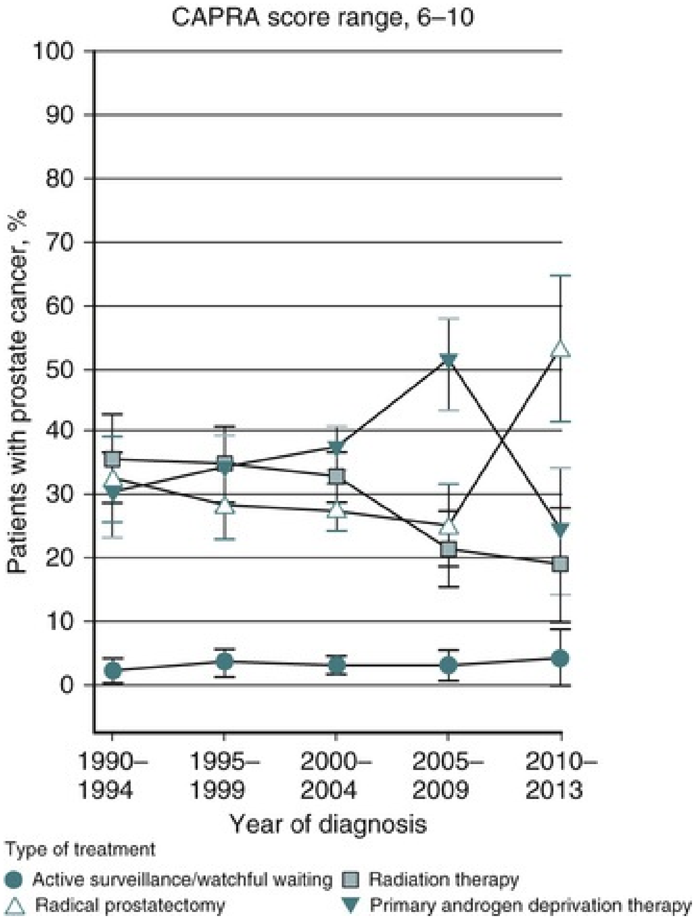

FIG. 159.5 Treatment trends in the Cancer of the Prostate Strategic Urologic Research Endeavor (CaPSURE) Registry for men with CAPRA score range 6–10. Error bars indicate 95% confidence intervals. (Modified from Cooperberg MR, Carroll PR. Trends in management for patients with localized prostate cancer, 1990–2013. *JAMA* 314[1]:80–82, 2015.)

Natural History

Active surveillance, with deferred treatment when necessary, is a viable treatment alternative in men with prostate cancer. Multiple studies have suggested that disease-specific mortality is low and primarily associated with higher-grade and higher-stage disease. Even in those low-risk cancers, however, an increased and unexpected progression of disease and associated prostate cancer mortality may be seen during an extended period (Johansson et al., 2004). In men with higher-risk disease characteristics, it has been recognized that disease progression occurs more rapidly and that some form of intervention is typically warranted in healthy patients. Nevertheless, the indications for active surveillance are expanding, and appropriate selection may be facilitated by novel genomic tests (Cooperberg et al., 2011; Cary and Cooperberg, 2013).

Few reports address the specific question of outcome in men with locally advanced cancers merely observed for a prolonged period. Older studies such as that from Nesbit and Plumb (1946) have little relevance to current disease management. Other studies have included only a small number of patients with higher clinical stage. A range of clinical progression (22% to 75%), local progression (22% to 84%), and development of distant metastases (27% to 56%) has been reported during 5 and 10 years of follow-up. **Overall survival ranging from 10% to 92% at 5 years and from 14% to 78% at 10 years is reported for patients who harbor cancers of high grade or stage.** The Veterans Administration Cooperative Urological Research Group (VACURG) study reported a 58% overall 5-year survival in 248 men with clinical stage III disease treated with placebo (Byar, 1973). Comparable survival outcomes were reported within the Medical Research Council (MRC) study (Adib et al., 1997) randomizing previously untreated patients with locally advanced, nonmetastatic disease (*n* = 501) to early or delayed AD therapy (castration or luteinizing hormone–releasing hormone [LHRH] agonist). The median time to clinical progression and death from prostate cancer in the 244 patients receiving delayed treatment was 10 months and 48 months, respectively.

In the analysis from Chodak et al. (1994), grade 3 tumors were significantly associated with disease-specific mortality (risk ratio 10.04) in men treated conservatively, compared with low-grade (grade 1) cancers. The 10-year disease-specific survival was 87% in men with grade 1 or grade 2 tumor and 34% with grade 3 tumor, with metastasis-free survival of 81% for grade 1, 58% for grade

2, and 25% for grade 3 diseases. Johansson et al. (1997) prospectively observed 642 men with prostate cancer diagnosed between 1977 and 1984 with any stage of disease. Of those men with clinically localized disease, 11% died of prostate cancer, with corrected 15-year survival comparable for those who received initial and deferred treatment. Conversely, the corrected 15-year survival was 57% in patients with locally advanced cancer. Approximately one-half of men had well-differentiated tumors, and only 6% of these men died of prostate cancer. Death from prostate cancer increased with moderately differentiated (17%) and poorly differentiated (56%) disease. These data are summarized in Table 159.3.

From Johansson JE, Holmberg L, Johansson S, et al. Fifteen-year survival in prostate cancer. A prospective, population-based study in Sweden. *JAMA* 277(6):467–471, 1997.

Albertsen et al. (1998) reported the long-term outcomes of watchful waiting in 767 men identified from the Connecticut Tumor Registry with clinically localized prostate cancer (1971 to 1984). The 15-year disease-specific mortality in men with Gleason sum 6 was 18% to 30%, compared with the 25% to 59% risk for death from other causes. The chances of death from prostate cancer increased with Gleason score 7 (42% to 70%) and 8 to 10 (60% to 87%). It is likely that a significant proportion of this cohort had non–organ-confined disease because none of the men underwent PSA testing, therefore they probably had more advanced stages of disease compared with contemporary cohorts. In contrast with the report from Johansson et al. (2004), the annual mortality rate from low-grade prostate cancer appears to remain stable beyond 15 years after diagnosis (Albertsen et al., 2005) (Fig. 159.6). **Men with high-risk prostate cancer, including those with locally advanced disease, are at significant risk for disease progression and disease-specific death if left untreated.**

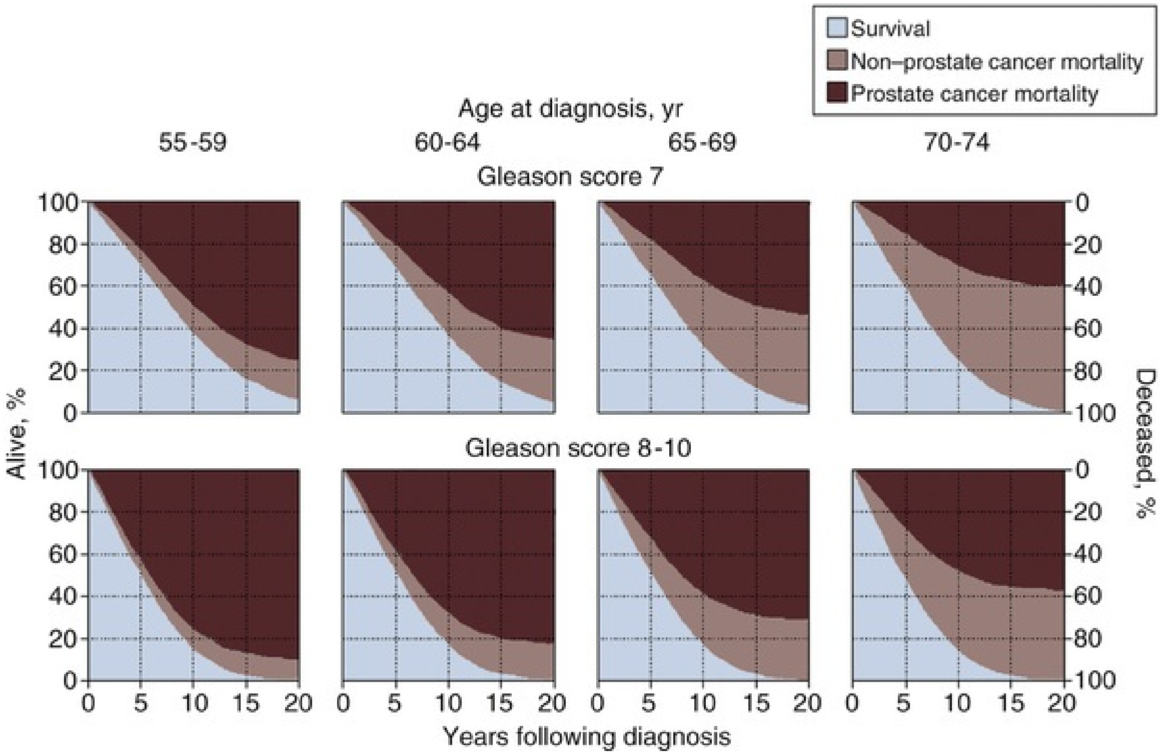

FIG. 159.6 Prostate cancer mortality as a factor of Gleason grade and age at diagnosis in men managed conservatively. *Brown-shaded areas* represent proportion of patients dying of prostate cancer. *Light brown–shaded areas* represent death from competing causes. *Light-blue areas* represent proportion of patients alive. (Modified from Albertsen PC, Hanley JA, Fine J. 20-year outcomes following conservative management of clinically localized prostate cancer. *JAMA* 293[17]:2095–2101, 2005.)

Indeed, there is undertreatment in some men with high-risk disease. Within the National Prostate Cancer Register of Sweden, the proportion of men younger than 70 years of age with high-risk, nonmetastatic prostate cancer receiving definitive therapy varied with life expectancy as estimated by age and Charlson comorbidity index (Bratt et al., 2015). In contrast, use of surgery and RT in otherwise healthy men in their seventies was significantly lower despite comparable life expectancy. In men older than 70 years of age with life expectancy greater than 10 years, RT and surgery were applied in only 40% and 10% of cases, respectively. Comparable findings were reported within the UK from the National Prostate Cancer Audit (Sujenthiran et al., 2017).

Radical Prostatectomy

The use of radical prostatectomy for management of locally advanced prostate cancer had decreased 10 years ago. In part, the shift in paradigm was caused by the recognition that prostatectomy alone is often insufficient. In addition, improved risk assessment has permitted better identification of these patients before treatment. Advances in delivery of RT and recognition that combined modality treatment (e.g., RT and AD) improved outcomes compared with monotherapy have further contributed to the migration away from surgery for high-risk and locally advanced tumors. Nevertheless, radical prostatectomy can cure some men with high-risk disease features, and the addition of adjuvant and combined therapy may further improve outcomes of surgery alone; this is reflected by increased rates of prostatectomy for more aggressive disease.

Surgery for Clinical Stage T3 Prostate Cancer

Several series report outcomes of radical prostatectomy for clinical stage T3 tumors (Table 159.4). In examining all reports, **overall survival ranges from 64% to 96% at 5 years, 12.5% to 72% at 10 years, and 20% to 51% at 15 years after treatment.** Earlier data reflected less accurate risk assessment and a potentially greater number of patients with unsuspected lymph node metastases and associated earlier progression and death. Less variability exists in more contemporary cohorts, in which the **disease-specific survival rates are 85% to 92% and 79% to 82% at 5 and 10 years, respectively, regardless of adjuvant therapy.**

Pound et al. (1999) found that a reasonable outcome was possible after prostatectomy for clinical stage T3a disease, with a 52% 8-year recurrence-free survival. Similarly, Ward and Zincke (2003) reported 5- and 10-year disease-free survival of 60% and 44%, respectively, without application of adjuvant AD. Freedom from local or systemic disease at 5 and 15 years after surgery was 73% and 67%, respectively (Ward et al., 2005). In the 812 patients from the series by Lerner et al. (1995), 10-year disease-specific survival was 80%, with only 31% of men with clinical stage T3 disease dying of prostate cancer 15 years after radical prostatectomy. It is unclear, however, whether surgical intervention improves survival compared with alternative treatment strategies. Another interesting observation from the Mayo Clinic was that clinical *overstaging* was identified in 27% of patients, consistent with other reported rates of 7% to 26%, suggesting that uniformly excluding patients from prostatectomy on the basis of clinical staging may not be appropriate (Ward et al., 2005). The long-term update from this series demonstrated local recurrence-free, systemic progression-free, and disease-specific survival of 76%, 72%, and 81%, respectively, at 20 years (Mitchell et al., 2012). Gerber et al. (1997) reviewed results in 298 men with clinical stage T3 disease undergoing radical prostatectomy and pelvic lymphadenectomy. Although the overall 10-year disease-specific survival was 57%, an apparent benefit of radical prostatectomy in some men with locally advanced disease was suggested by the increased survival (70%) in those who actually underwent prostatectomy and lymph node dissection. In a high-risk cohort undergoing surgery between 1987 and 2009, 37% had specimen-confined disease (pT2–pT3a), and a nomogram was developed incorporating PSA level, age, clinical stage, and biopsy Gleason sum to predict this with 72% accuracy (Briganti et al., 2012). **Many men with clinical stage T3 disease have regional spread and may not benefit from prostatectomy; however, select patients (e.g., lower-volume disease) may benefit because local control may be achieved in most, and complete cancer excision is possible in some men.**

Biochemical progression after radical prostatectomy is difficult to assess, given the frequent use of adjuvant therapy (e.g., RT or AD). Without the use of secondary treatment, 5-year biochemical relapse is higher than 60% (van den Ouden et al., 1998). In other series with variable use of adjuvant therapy, 5- and 10-year biochemical progression was observed in 42% to 49% and 59% to 62%, respectively. The impact of adjuvant therapy may be minimal with respect to clinical progression (i.e., biopsy-proven local recurrence or objective distant metastasis) after radical prostatectomy. Rates of clinical progression at 5, 10, and 15 years are 12% to 45%, 39% to 49%, and 50% to 71%, respectively.

Outcomes of Prostatectomy for Pathologically Advanced Disease

A significant minority of patients undergoing radical prostatectomy for clinically organ-confined disease will ultimately be found to have *pathologic* evidence of spread outside the prostate. Although these patients may be expected to have progression and survival rates comparable with those of patients with clinically advanced disease, as defined by grade and serum PSA level, those men who present with clinical stage T3 disease are likely to have greater tumor volume, higher grade, and increased likelihood of regional spread. Currently, the majority of men undergoing prostatectomy for pathologically advanced disease are categorized as high risk on the basis of serum PSA value or biopsy Gleason score. Nevertheless, there is overlap in the groups of men undergoing radical prostatectomy for *clinical* stage T3 and *pathologic* stage T3.

As discussed, pathologic stage after radical prostatectomy provides important prognostic information and is a powerful predictor of outcome, considering all clinical and pathologic factors (Fig. 159.7). **The presence of focal or established extracapsular extension increases the rate of clinical progression from 7% for organ-confined disease to 18% and 35%, respectively, at 5 years.** Patients with evidence of seminal vesicle invasion or lymph node metastasis are highly likely to develop clinical progression (86% and 95%, respectively) after radical prostatectomy. In men undergoing radical prostatectomy for clinically organ-confined disease, Hull et al. (2002) reported 5-year PSA-free survival of 95%, 76%, 37%, and 18% for men with pathologic organ-confined disease, extracapsular extension, seminal vesicle invasion, and positive lymph nodes, respectively. In a multivariate analysis, pathologic parameters increasing the relative risk (RR) for progression included extracapsular extension (RR 2.17 to 2.72), seminal vesicle involvement (RR 2.61), and lymph node involvement (RR 3.31). The presence of a positive surgical margin was associated with the greatest RR (4.37, 95% confidence interval [CI] 2.90 to 6.58). This reinforces the concept that complete surgical removal of all prostatic tissue, regardless of clinical or pathologic stage, should be accomplished when prostatectomy is undertaken. Even with seminal vesicle invasion, however, men without concomitant lymph node involvement can achieve 15-year disease-specific survival and BDFS rates of 81% and 32%, respectively (Secin et al., 2006).

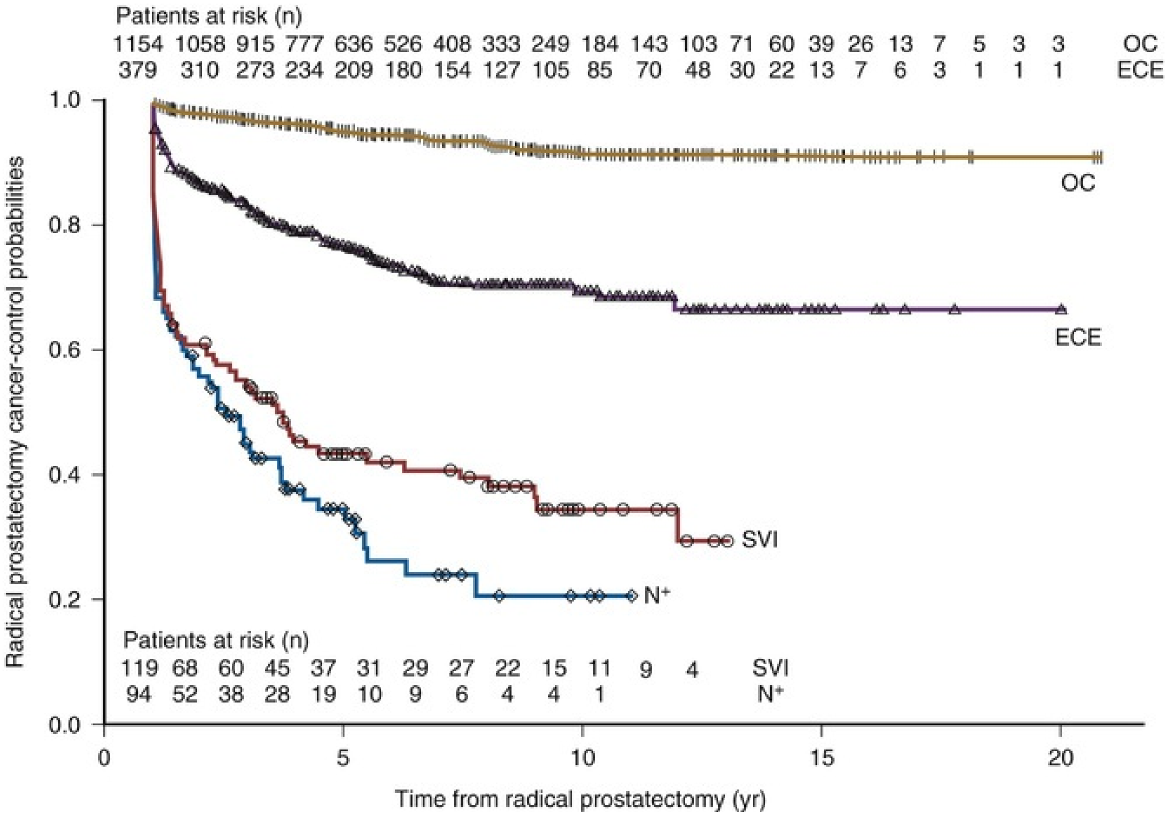

FIG. 159.7 Probabilities of cancer control after radical prostatectomy based on pathologic stage. *ECE,* extracapsular extension; *N*$^+$, node positive; *OC,* organ confined; *SVI,* seminal vesicle invasion. (Modified from Bianco FJ Jr, Scardino PT, Eastham JA. Radical prostatectomy: long-term cancer control and recovery of sexual and urinary function [“trifecta”]. *Urology* 66[5 Suppl]:83–94, 2005.)

Biochemical progression after prostatectomy for pathologically advanced tumors depends on the definition applied. Five-year rates of biochemical recurrence have been as high as 65% to 72% when a PSA threshold of 0.2 ng/mL is used; less stringent thresholds such as 0.4 ng/mL may yield recurrence rates of 26% at 5 years and at least 50% at 10 years. In a cohort of 747 men with pT3bN0 tumors identified after prostatectomy, the 10-year biochemical recurrence–free, metastasis-free, and disease-specific survival rates were approximately 25%, 70%, and 80%, respectively (Pierorazio et al., 2011). Seminal vesicle involvement not only increases the risk for biochemical recurrence but also significantly increases the risk for local recurrence after radical prostatectomy. With prolonged follow-up, Hawkins et al. (1995) reported local recurrence in nearly one-half of patients. This risk appears to be lower in contemporary series of patients because of improved selection of patients for surgery, improved surgical technique, and earlier use of secondary treatment, either as adjuvant therapy or at the time of biochemical relapse. The minimally invasive approach has been increasingly applied in higher-risk cases, and overall the outcomes appear reasonable and comparable to the open approach. Both oncologic and functional outcomes have not been reported to be significantly different, although variability in performing and the extent of pelvic lymphadenectomy require further study (Pierorazio et al., 2013; Punnen et al., 2013).

Predictive models have permitted preoperative estimation of PSA-free survival after prostatectomy. Patients with higher biopsy Gleason score and more elevated serum PSA level are at increased risk for failure after surgery. **Overall, the actuarial PSA-free survival after surgery in high-risk men is approximately 50% at 5 to 7 years.** The validity of the Kattan preoperative nomogram was examined in a community-based cohort of patients undergoing radical prostatectomy (Greene et al., 2004). Interestingly, although the overall concordance index (.68) supported the applicability of the tool to a broad spectrum of patients, the nomogram underestimated recurrence in lower-risk men and overestimated recurrence in men at higher calculated risk. Indeed, up to one-half of men with Gleason sum 8 to 10 or higher PSA level (>20 ng/mL) may achieve prolonged disease-free survival with prostatectomy alone. Further refinements of risk assessment and novel markers will help determine which high-risk men and locally advanced tumors truly benefit from aggressive surgical intervention, either alone or in combination with other therapy.

Outcomes of Prostatectomy for Node-Positive Disease

Despite poorer outcomes with node-positive disease, there is renewed interest in aggressive local therapy, including prostatectomy, given contemporary multimodal approaches, longer life expectancy, and potential oncologic and symptomatic benefits of surgical removal of the primary tumor. Selection of appropriate patients remains to be determined and may be aided by novel preoperative imaging modalities such as ^{68}Ga-PSMA-11 PET, identifying men with limited metastatic disease or where complete excision of gross disease (e.g., pelvic nodes) may be possible. An important question is whether surgery in this setting is feasible with acceptable morbidity. Several studies have demonstrated acceptable rates of complications and urinary incontinence after cytoreductive prostatectomy for M1 disease (Heidenreich et al., 2015; Sooriakumaran et al., 2016). In addition, performing surgery after neoadjuvant systemic therapy, a likely scenario, does not appear to increase the risk for perioperative complications, and CALGB 90203 should address this question (Williams et al., 2016).

After long-term follow-up of 88 men with node-positive disease after surgery, overall survival was 51% at 10 years (Seiler et al., 2014). In those with a single positive node, nearly one-half did not exhibit clinical progression and 57% did not require AD, with over 80% disease-specific survival. Touijer et al. (2014) reported similar findings in a group of men with node-positive disease who did not receive adjuvant AD or RT. Ten-year overall and disease-specific survival were 60% and 72%, respectively, and rates of freedom from metastases and biochemical recurrence were 65% and 28%, respectively. Gleason grade (>8) and greater number of lymph nodes (>3) predicted poorer outcome. Gandaglia et al. (2017) reported on a selected cohort of 11 men with oligometastatic disease (≤5 bone metastases) treated with prostatectomy and extended lymph node dissection, where 91% had node-positive disease and adjuvant AD was administered in nearly all patients. At median follow-up of 63 months, progression-free and disease-specific survival rates were 45% and 82%, respectively. The findings from Nini et al. (2015) also suggest a subset of node-positive patients where surgery may be appropriate. Among those with biochemical recurrence after surgery, nearly one-third had local and/or nodal disease as the first site of clinical recurrence, and this was associated with significantly improved disease-specific survival (79% at 5 years). Many ongoing clinical trials are specifically examining the role of local therapy in the setting of oligometastatic disease and should inform us regarding surgery for node-positive prostate cancer.

Neoadjuvant Androgen Deprivation

To improve outcomes of radical prostatectomy in men with locally advanced or high-risk tumors, several investigators have assessed the use of neoadjuvant androgen deprivation (NAD) before radical prostatectomy. In 1944, Vallet reported performing radical perineal prostatectomy after orchiectomy in a 59-year-old man with prostate cancer. Others reported the use and efficacy of diethylstilbestrol (DES) before surgery. In 1964, Scott evaluated the results of NAD in 31 men who were observed for 10 years. The majority of patients (52%) were alive and free from clinical recurrence. The prospective randomized trials of NAD in patients with stage cT1–T3 prostate cancer before radical prostatectomy are summarized in Table 159.5.

Key Points: Radical Prostatectomy

- Radical prostatectomy alone can result in disease-free survival in at least one-half of men at 8 to 10 years despite clinically advanced disease.
- The risk for cancer recurrence after surgery can be quantitated on the basis of pathologic stage, cancer grade, and surgical margin status.
- NAD therapy before radical prostatectomy does not appear to improve disease-specific or overall survival.

Various measures of outcome have been evaluated in these studies, including changes in digital rectal examination (clinical stage), appearance of tumor on imaging, detection of micrometastatic or circulating cancer cells, and pathologic features such as T stage, surgical margin and lymph node status, and histopathologic changes. Ultimately, the utility of NAD must be assessed by its impact on disease-specific survival or its current surrogate, BDFS. It is clear that NAD affects tumor behavior and biology, evaluable by changes in metabolic patterns of atrophy on magnetic resonance spectroscopy, lowering of serum PSA level, and histologic atrophy (fibrosis, vacuolization, glandular collapse). Studies have demonstrated that significant reductions in prostate volume (30% to 50%), tumor volume, and PSA level (90%) are consistently noted, with maximal effects occurring during the first 2 months of treatment. However, conflicting results have been reported with respect to pathologic downstaging after NAD in patients with clinical stage T3 cancer. **Overall, only 20% of such patients have organ-confined disease at the time of radical prostatectomy despite clinical downstaging in 32% to 90%.** Schulman et al. (2000) described 402 patients with cT2–T3N0M0 tumors randomized to either radical prostatectomy alone or 3 months of total androgen blockade followed by surgery. Pathologic downstaging was seen more frequently in the neoadjuvant group (15%) than in the prostatectomy-alone group (7%; $P < .01$); however, in men with cT3 disease, there was no difference in pathologic downstaging ($P = .18$) or the incidence of lymph node metastases ($P = .36$) in the neoadjuvant and surgery-alone cohorts. Thus whereas clinical downstaging may occur frequently, **pathologic downstaging is significantly less common after NAD, ranging between 8% and 31%.** Most studies do not show decreased seminal vesicle invasion (Table 159.6). Similarly, rates of lymph node metastases are not altered, with the incidence varying between 3.3% and 16% in both the prostatectomy-alone and NAD groups.

NAD, neoadjuvant androgen deprivation; *NR,* not reported.

Klotz et al. (2003) provided long-term follow-up (median, 6 years) of a prospective randomized trial comparing 3 months of NAD before prostatectomy and surgery alone. There was no overall benefit of NAD as measured by biochemical recurrence (34% to 38%), although in the subgroup of men with PSA level above 20 ng/mL, those receiving NAD had greater PSA-free survival (53%) compared with those undergoing prostatectomy alone (35%, $P = .015$). Southwest Oncology Group (SWOG) 9109 was a phase II feasibility study of 16 weeks of goserelin and flutamide before radical prostatectomy in men with T3–T4N0M0 prostate cancer (Powell et al., 2002). Of the 55 patients who underwent prostatectomy, 31% had seminal vesicle invasion and 19% had lymph node metastasis. Organ-confined disease was identified in 67% of cases. At median follow-up of 6.1 years, 5-year progression-free and overall survival estimates were 70% and 90%, respectively. The study demonstrated the feasibility of 4 months of AD before surgery, with acceptable morbidity and outcomes comparable with RT for this population of patients. Extended follow-up at a median of 10.6 years revealed that only 55% had disease progression, with progression-free survival of 40% and overall survival of 68% (Berglund et al., 2012).

Studies have also examined the incidence of positive surgical margins in those with cT3 disease. Witjes et al. (1997) reported similar rates of positive margins in men receiving NAD and those undergoing radical prostatectomy alone (43% and 59%, respectively; $P = .14$). Van Poppel et al. (1995) did not find a statistically significant difference between these groups with respect to positive margins—41.3% in the neoadjuvant cohort and 44% in the surgery-alone group. SWOG 9109 reported positive surgical margins in 30% of patients. In contrast, the randomized and nonrandomized studies of NAD in men with lower clinical stage (cT1–T2) clearly demonstrate a reduction in the rate of positive surgical margins. This advantage has not translated into improved long-term PSA-free survival. **For locally advanced tumors (specifically cT3), current data, both retrospective and prospective, do not support a significant benefit of NAD before surgery (Table 159.7).**

mo, months; *NAD,* neoadjuvant androgen deprivation; *PSA,* prostate-specific antigen; *yr,* year.

The apparent lack of benefit of NAD before radical prostatectomy in men with both lower-stage and locally advanced prostate cancer may be caused by a number of factors. It has been suggested that 3 months of AD may be insufficient to cause an improvement in disease-free survival compared with prostatectomy alone. Meyer et al. (1999) followed 680 men treated with radical prostatectomy, of whom 292 received NAD. Although there was no difference in risk for biochemical recurrence between the two groups, patients receiving both an LHRH agonist and antiandrogen for more than 3 months had a significantly lower risk for PSA failure than did those treated with surgery alone (hazard ratio [HR] 0.52, 95% CI, 0.29 to 0.93). Subsequently, the Canadian Urologic Oncology Group randomized patients with clinically localized disease to either 3 or 8 months of NAD before radical prostatectomy (Gleave et al., 2001). In the 500 patients with pathologic staging, positive surgical margins were identified in 23% of the 3-month group and 12% of the 8-month group (*P* = .011); organ-confined disease was found in 68% and 80% of the 3-month and 8-month groups, respectively (*P* = .0019). In addition, the rate of non–specimen-confined disease or lymph node extension was greater in the 3-month group (25.6%)

compared with the 8-month group (12.6%). However, despite evidence of continued biochemical and pathologic regression of the tumor between 3 and 8 months, no significant difference in PSA recurrence rates was observed at 4 years. Ongoing studies are evaluating the potential utility of other AD agents before surgery, including degarelix, abiraterone, and enzalutamide.

Neoadjuvant Chemotherapy and Chemotherapy–Hormonal Therapy

The role of chemotherapy in the treatment of prostate cancer has primarily been limited to men with the most advanced disease. Taxanes, alone or in combination with other agents, have proved effective in those with hormone-refractory prostate cancer, with significant PSA declines (>50%) in more than one-half of patients and measurable disease response in 28% to 75% (Oh, 2004). Mitoxantrone plus low-dose steroids has shown benefit in pain relief compared with steroids alone and is approved for use in hormone-refractory disease (Kantoff et al., 1999; Tannock et al., 1996). On the basis of these observations, interest has increased in earlier use of chemotherapy in high-risk patients or those with locally advanced disease. These studies are summarized in Table 159.8.

D, docetaxel; *E/VP-16,* estramustine + etoposide; *KAVE,* ketoconazole + doxorubicin/vinblastine + estramustine; *NAD,* neoadjuvant androgen deprivation; *PSA,* prostate-specific antigen; *TEC,* paclitaxel + estramustine + carboplatin.

Pettaway et al. (2000) treated 33 higher-risk patients with a 3-month combination regimen consisting of two 6-week cycles of ketoconazole and doxorubicin alternating with vinblastine and estramustine. In addition, concurrent AD was accomplished with an LHRH agonist and an antiandrogen. Lower pathologic stage was found in 18% of patients with cT3 disease, and the overall positive surgical margin rate of only 17% suggests that the regimen may have improved the ability to resect the cancer above that achieved with NAD alone. A second report of chemotherapy and hormone therapy before surgery combined 4 to 6 months of NAD with paclitaxel, estramustine, and carboplatin in patients with androgen-dependent, high-risk prostate cancer (Konety et al., 2004). No patients were downstaged to pT0 after neoadjuvant therapy, and organ-confined disease was reported in 36%, with a 22% positive surgical margin rate. Overall, 45% remained without biochemical relapse, defined as PSA level above 0.05 ng/mL on three occasions, at median follow-up of 29 months, and no patient has had documented local recurrence. At 43 months of follow-up, Chi et al. (2008) reported a 3% complete pathologic response rate and a distant relapse rate of 30% in patients treated with NAD and docetaxel.

Other centers have used chemotherapy without concurrent NAD. At the Cleveland Clinic, 16 patients with locally advanced disease (clinical M0) underwent three cycles of oral estramustine and etoposide and subsequent surgery (Clark et al., 2001). Although grade 3 or grade 4 toxicity was seen in 34% of patients, surgery was not delayed in any individual, and surgical outcomes were comparable with those in series of prostatectomy without neoadjuvant therapy. With a median follow-up of 14 months, 88% were free from disease, and the early PSA failures occurred in the two patients with lymph node metastases.

Single-agent docetaxel is well tolerated before radical prostatectomy, with minimal toxicity (Dreicer et al., 2004; Oh et al., 2001). No cases of complete pathologic response were observed, but no lymph node metastases were identified in one series, whereas the other reported 11% with organ-confined disease. Two-thirds and 24% of patients, respectively, experienced a more than 50% reduction in PSA level in response to docetaxel alone. Similar observations have been made using a novel nanoparticle-based formulation of paclitaxel, with no complete pathologic responses (Shepard et al., 2009). Combination therapy with mitoxantrone or estramustine has been reported in small numbers. Garzotto et al. (2010) treated 57 men with docetaxel and dose-escalated mitoxantrone during the 16 weeks before surgery. One-half of patients were free from relapse at 5 years, and the rate of positive surgical margins was 33%. Agents described in recent reports include granulocyte-macrophage colony-stimulating factor and thalidomide (Garcia et al., 2008), and the epidermal growth factor receptor inhibitor gefitinib (Vuky et al., 2009). It remains to be determined whether new, targeted agents (e.g., custirsen) and immunotherapy (e.g., sipuleucel-T, ipilimumab, PD-1/PD-L1 inhibitors) will play a role in the neoadjuvant setting.

Adjuvant Radiation Therapy

Withholding regional or systemic therapy until after the prostate has been removed may (1) prevent delay in time to surgery, (2) reduce operative morbidity, and most importantly (3) identify those men with adverse pathologic features or evidence of residual disease who truly need additional therapy, thereby avoiding overtreatment in those found to have more favorable disease. The selection of appropriate adjuvant therapy remains difficult because knowledge of the ultimate site of failure (discriminating local-regional from distant recurrence) determines the actual type, timing, and efficacy of such intervention.

Until recently, adjuvant RT was not clearly demonstrated to be beneficial after radical prostatectomy; older studies demonstrated no impact on development of distant metastasis or disease-specific survival, and more recent data show improved biochemical control. Table 159.9 summarizes selected comparative series of adjuvant RT for pathologically advanced disease. In the matched-pair analysis of Valicenti et al. (1999), early adjuvant RT was administered within 3 to 6 months of surgery with undetectable PSA; control subjects were observed until PSA recurrence. The reduction in risk for PSA relapse was 88% after adjuvant RT, with 5-year PSA-free survival of 89%. Anscher et al. (1995) provided long-term follow-up (median, 10 years) in 46 patients receiving adjuvant RT after radical prostatectomy for pT3–T4 tumors. At 10 and 15 years, overall survival and disease-free survival in the RT group were 62% and 62% and 55% and 48%, respectively; these were not statistically different from the rates in the group not receiving adjuvant RT. In addition, development of distant metastases was comparable in the two cohorts. Nevertheless, local control was better after adjuvant RT (82% at 15 years) compared with surgery alone (53%).

The use of adjuvant RT is associated with a range of BDFS from 50% to 88% at 5 years. This appears to be an improvement (30% to 50%) compared with the results of surgery alone in high-risk patients. Nevertheless, the benefit of adjuvant RT needed to be proven in appropriately designed clinical trials, of which the European Organisation for Research and Treatment of Cancer (EORTC) 22911 (Bolla et al., 2005) and SWOG 8794 (Thompson et al., 2006) have been reported. Both studies randomized patients with pathologically advanced disease, defined as extraprostatic extension (pT3) and/or positive surgical margins without lymph node metastasis, to either immediate RT or observation after surgery. In EORTC 22911, immediate RT was associated with improved BDFS (74% vs. 53% without RT, $P < .001$) at 5 years. Similarly, SWOG 8794, with median 10.6 years of follow-up, supported immediate RT with a nearly 50% reduction in biochemical recurrence (35% vs. 64% without RT, $P < .001$) in those with PSA less than 0.4 ng/mL after prostatectomy. In addition, adjuvant RT significantly reduced the risk for clinical local recurrence in both trials. SWOG 8794 demonstrated a surprisingly low risk for metastatic disease (16%) in patients with adverse pathologic features that was further reduced with adjuvant RT (7%) (Swanson et al., 2007), and improved freedom from subsequent AD. Moreover, both metastasis-free and overall survival were improved with adjuvant RT (HR 0.71 and 0.72, respectively) (Thompson et al., 2009). A third randomized, controlled trial studying adjuvant RT for pT3N0 tumors after prostatectomy achieving an undetectable PSA confirmed the benefit with respect to BDFS (HR 0.53) (Wiegel et al., 2009).

The decision to administer adjuvant RT is often based on various adverse pathologic features, not all of which carry the same prognosis; indeed, SWOG 8794 combined extracapsular extension, seminal vesicle invasion, and positive surgical margin within a single classification. Thus it is difficult to assess the outcomes of adjuvant RT when the populations are composed, variably, of those with positive surgical margins, extracapsular extension, seminal vesicle invasion, or a combination of these features. Those men with positive surgical margins are at an increased risk for biochemical recurrence. A decision analytical model examining this question demonstrated that the benefit may be limited to those with high likelihood of recurrent local, rather than distant, disease; thus initial RT was recommended for patients with low- to intermediate-grade disease without evidence of seminal vesicle invasion (Grossfeld et al., 2000). This report suggested that adjuvant RT should be considered in those patients with extensive or multiple positive surgical margins. Secondary analyses of EORTC 22911 also support the role of immediate RT in the specific subset with positive surgical margins (Van der Kwast et al., 2007). The treatment benefit of adjuvant RT was primarily seen in patients with positive surgical margins (HR 0.38, $P < .0001$), whereas no benefit was observed in those with negative margins independent of other risk factors. However, the report from Stephenson et al. (2004) suggests that the application of adjuvant RT in a broader group of men may be beneficial; 501 men received salvage RT for biochemical recurrence after radical prostatectomy, and 50% experienced disease progression after treatment at a median follow-up of 45 months. Although higher Gleason score and seminal vesicle invasion were poor prognostic variables in predicting response to salvage RT, selected patients with high-grade disease or other adverse features (e.g., rapid PSA doubling time) could still achieve a durable response. Indeed, more than one-half of patients with Gleason sum 8 to 10 and positive surgical margins had a PSA nadir of 0.1 ng/mL or less without subsequent rise above this level. **Thus early use of secondary therapy, be it RT or AD, may be beneficial in locally advanced tumors, and at the time of biochemical recurrence in select patients.** However, the optimal timing and how these interventions may differentially affect local control, development of distant disease, and survival remain to be determined. Trock et al. (2008) reported an improvement in overall survival in patients with pT3 disease receiving salvage RT, with 5-year overall survival of 98%.

In general, men with seminal vesicle invasion are at significant risk for distant metastasis and may not benefit from local or regional RT; nevertheless, some men with pT3b disease may have local recurrence alone. Valicenti et al. (1998b) identified a group of 53 men with pT3bN0 disease undergoing radical prostatectomy, with 35 achieving undetectable PSA after surgery. The BDFS (3 years) in the 15 patients receiving adjuvant RT was 86% compared with 48% in the 20 men who were observed ($P = .01$). In EORTC 22911, there was no statistically significant predictive impact of seminal vesicle invasion on the benefit from RT as measured by BDFS, regardless of whether PSA was less than or greater than 0.2 ng/mL after surgery (Van der Kwast et al., 2007). However, even with pT3b disease, there was a benefit of adjuvant RT in patients with positive surgical margins. Men in SWOG 8794 with seminal vesicle invasion receiving RT had improved 10-year BDFS (36% vs. 12% for observation) but no significant improvement in metastasis-free and overall survival. Conversely, subgroup analysis of the ARO trial suggested that extracapsular extension without infiltration of the seminal vesicles was a predictor of more favorable outcome with RT (Wiegel et al., 2014). **On the basis of limited data, it appears that men with seminal vesicle invasion who achieve a low PSA level (<0.3 ng/mL) after prostatectomy or have positive surgical margins may be a more favorable group in whom adjuvant RT may be considered. Conversely, those men with more advanced disease never reaching an undetectable PSA level generally constitute a poor prognostic group likely harboring unrecognized lymph node or distant disease.** Novel genomic or biomarkers may help identify those most likely to benefit. Zhao et al. (2016) developed a score based on a 24-gene expression signature and found that those with a higher score who received postoperative RT were less likely to develop metastasis at 10 years, suggesting that this molecular signature may predict response to RT.

Traditionally, adjuvant RT has been delivered in lower doses compared with the dose for salvage therapy, with the range from 45 Gy to more than 60 Gy. Most contemporary series of adjuvant RT report doses greater than 60 Gy. Valicenti et al. (1998a) evaluated the dose response in a small number of patients ($N = 52$) receiving adjuvant RT for pT3N0 disease. The difference in 3-year BDFS between those treated with less than 61.2 Gy (64%) and more than 61.2 Gy (90%) was statistically significant ($P = .015$), suggesting that higher doses may be necessary. In 27 men with detectable PSA 6 months after prostatectomy, Schild et al. (1994) noted that RT doses of 64 Gy or more had improved 30-month freedom from failure (62%) compared with lower RT doses (17%; $P = .03$), supporting the hypothesis of a postoperative RT dose response similar to what has been observed for primary RT in prostate cancer (Schild et al., 1994).

The results from Radiation Therapy Oncology Group (RTOG) 0621 suggest a benefit of combined local and systemic therapy in the adjuvant setting (Hurwitz et al., 2017). High-risk men (96% pT3–T4, 82% Gleason ≥8) received 6 months of AD along with RT and 6 cycles of docetaxel. The 3-year freedom from progression was 73%, exceeding the expected rate of 50% and supporting phase III trials of similar design.

Key Points: Adjuvant Radiation Therapy

- Adjuvant RT improves local control and reduces biochemical relapse in selected patients after radical prostatectomy and likely improves metastasis-free and overall survival.
- The benefit of adjuvant RT may be greatest in cases with positive surgical margins.
- Improved outcomes of adjuvant RT are associated with dose escalation (64 Gy).

Adjuvant Androgen Deprivation

Indirect evidence from the MRC and VACURG trials suggesting a benefit of early AD compared with delayed AD in men with various stages of prostate cancer served as the impetus for studying adjuvant AD after radical prostatectomy. In addition, evidence of a benefit of continued AD after therapeutic RT supports a potential role for combined systemic treatment after local therapy in the form of prostatectomy. However, limited clinical data are currently published on this issue in men with locally advanced tumors.

Beyer et al. (1993) retrospectively reviewed the outcomes of 86 patients undergoing radical prostatectomy and any form of adjuvant therapy (89% endocrine treatment). In the subset of patients with stage pT3N0 tumors, adjuvant treatment did not demonstrate an advantage with respect to time to progression or survival. Cheng et al. (1993) reviewed the Mayo Clinic experience with 1035 patients undergoing radical prostatectomy for pathologic stage C prostate cancer; a significant number ($N = 103$) received adjuvant AD with orchiectomy. Adjuvant therapy of any type (AD or RT) decreased the rate of progression but did not improve disease-specific or overall survival, with no difference between the two modalities. Prayer-Galetti et al. (2000) presented data on 201 men with pT3 disease receiving adjuvant goserelin, demonstrating a 25.4% improvement in disease-free survival at median follow-up of 5 years ($P < .05$).

Recent publications provide some evidence supporting a benefit of early AD after radical prostatectomy in high-risk men with locoregional disease spread. Zincke et al. (2001) retrospectively reviewed data on men with stage pT3b cancer and found that early, adjuvant AD positively affected time to progression and disease-specific survival. These findings were true not only with seminal vesicle invasion but also with limited lymph node disease, with a 10-year cause-specific survival of 94% after prostatectomy and adjuvant AD with a single positive lymph node. Similar findings arose from the Eastern Cooperative Oncology Group study 7887 randomizing men with nodal metastases after radical prostatectomy (cT1–T2 disease) to immediate (adjuvant) or delayed AD (Messing et al., 1999). At a median follow-up of 11.9 years, men receiving adjuvant AD had improved overall (HR 1.84), disease-specific (HR 4.09), and progression-free (HR 3.42) survival. A matched-pair analysis of men with pT2–4N1 disease treated with prostatectomy suggested that adjuvant AD plus RT yielded significantly higher disease-specific and overall survival rates at 10 years (86% and 74%, respectively) compared with adjuvant AD alone (70% and 55%, respectively) (Briganti et al., 2011). Touijer et al. (2018) compared the outcomes of node-positive men managed with observation, lifelong adjuvant AD, or adjuvant AD plus RT after prostatectomy. Better overall survival was observed for adjuvant AD with RT (HR 0.41–0.46), and higher-risk patients benefited more than lower-risk patients. Improved disease-specific survival was also associated with adjuvant AD plus RT, and AD alone increased the risk for other-cause mortality relative to observation (HR 3.05).

Radiation Therapy

The contemporary trend is to treat high-risk or locally advanced prostate tumors with methods other than surgery. Although a plethora of studies describe the results of RT for clinical stage C and T3 disease, many were performed before the widespread use of serum PSA determination for early detection and modern radiotherapy techniques for treatment, such as three-dimensional conformal RT, intensity-modulated RT, and whole-pelvis irradiation in addition to the prostate (Kupelian et al., 2003). In addition, contemporary data suggest that the optimal radiation dose is higher than that used in previous reports. In higher-risk patients, improved biochemical control has been observed with 81 Gy or more for external-beam RT (Zelefsky et al., 2011). An earlier dose-escalation trial demonstrated improved outcomes with 78 Gy compared with 70 Gy, with the greatest benefits in the high-risk group with PSA greater than 10 ng/mL (Kuban et al., 2008). In the treatment of men with locally advanced or high-risk prostate tumors, monotherapy with RT or permanent interstitial brachytherapy is likely to be inadequate. Yet it must be emphasized that the outcome measures with demonstrated benefit of AD plus RT compared with RT alone often do not include overall survival. The focus has shifted to improving outcomes by combining RT with AD, often in conjunction with whole-pelvis irradiation (Table 159.10).

TABLE 159.10

Trials of Androgen Deprivation With External-Beam Radiation Therapy

STUDY (AUTHOR, YEAR)	NUMBER OF PATIENTS	ELIGIBILITY	RT DOSE (Gy)	STUDY ARM	DISEASE-FREE SURVIVAL	OVERA SURVIV

comparing whole pelvic to prostate only radiotherapy and neoadjuvant to adjuvant total androgen suppression: updated analysis of RTOG 94-13, with emphasis on unexpected hormone/radiation interactions. *Int J Radiat Oncol Biol Phys* 69(3):646–655, 2007; lower survival with WP + aAD (*P* = .027).

aAD, adjuvant androgen deprivation; *cAD,* concurrent androgen deprivation; *mo,* month; *nAD,* neoadjuvant androgen deprivation; *p,* prostate; *PSA,* prostate-specific antigen; *RT,* radiation therapy; *WP,* whole pelvis; *yr,* year.

Overall survival after RT alone for stage C cancer is approximately 60% to 70% at 5 years and below 50% at 10 years. In high-risk patients, defined by individual parameters alone or in combination, the 5-year progression-free survival rates after RT are typically less than 50%.

Neoadjuvant Androgen Deprivation and Radiation Therapy

The theoretical benefits of AD before RT in men with locally advanced cancers are the ability to reduce target volume and the potential cytotoxic synergy of radiation and hormone manipulation. Several RTOG trials (75-06, 83-07, 85-19) examined the combination of AD and RT in locally advanced disease, suggesting that the regimen was tolerable and improved local tumor control. On the basis of this information, RTOG 86-10 was designed to compare short-term AD combined with RT with RT alone (Pilepich et al., 2001; Roach et al., 2008). The phase III trial randomized 471 men with cT2–T4 tumors (surface area >25 cm^2 on rectal examination) to either goserelin plus flutamide for 2 months before and during external-beam RT or RT alone. The 4 months of AD were associated with reduction in distant metastases and improvements in local control, disease-free survival, and disease-specific mortality. At 10 years, the disease-free survival in the AD plus RT and RT-alone groups was 11% and 3%, respectively ($P < .0001$), whereas disease-specific mortality was 23% and 36%, respectively ($P = .01$). No difference in overall survival between the two groups (43% AD plus RT vs. 34% RT) was found, although men with lower Gleason sum (2 to 6) appeared to have a survival benefit from combined AD and RT. In men with Gleason sum 7 to 10, no significant improvement was observed from AD with respect to locoregional control or survival. Subsequent analysis of RTOG 86-10 (Chakravarti et al., 2003) revealed that loss of p16 expression on immunohistochemistry was associated with reduced overall survival ($P = .039$), disease-specific survival ($P = .006$), and higher risk for local progression ($P = .0007$) and distant metastasis ($P = .026$); overall survival was not significantly associated ($P = .07$) in multivariate analysis. Other correlative studies of tissue from RTOG 86-10 found that the proliferative marker Ki-67 was significantly associated with distant metastasis and disease-specific survival but not with overall survival (Li et al., 2004).

Laverdière et al. (1997) made similar observations in a prospective randomized study of 120 men with cT2b–T4 disease. Treatments included (1) external-beam RT alone, (2) 3 months of NAD before RT, and (3) 3 months of NAD before RT and 6 months of adjuvant AD. Evidence of residual cancer on prostate biopsy was present in 62%, 30%, and 4% of the treatment arms, respectively, at 12 months and 65%, 28%, and 5%, respectively, at 24 months. BDFS at 12 and 24 months paralleled the biopsy data, with the difference between the neoadjuvant and adjuvant AD groups disappearing at 24 months. These observations not only support neoadjuvant and concurrent AD with RT but also suggest a benefit of prolonged AD. In a group of men randomized to either 3 or 8 months of NAD before RT, of whom 31% were categorized as high risk, longer NAD did not improve freedom from or pattern of failure; the only benefit of 8 months of NAD was improved 5-year disease-free survival (71% vs. 42%) (Crook et al., 2009). Long-term outcomes (median 10.6 years) from the Trans-Tasman Radiation Oncology Group (TROG) 96.01 trial demonstrated that 6 months of NAD before RT at 66 Gy was associated with reduced PSA and local progression and event-free survival (HR 0.51) in men with cT2b–4N0M0 prostate cancer (Denham et al., 2011). Although 3 months of NAD had no effect on distant progression or disease-specific and all-cause mortality, 6 months of treatment decreased rates of all three compared with RT alone (HR 0.49, 049, and 0.63, respectively). However, there does not appear to be a general benefit of more prolonged AD before RT. RTOG 9910 randomized 1489 men with intermediate-risk disease to either 8 or 28 weeks of NAD along with 8 weeks of AD concurrent with RT (Pisansky et al., 2015). No differences between the two groups were observed with respect to disease-specific and overall survival, locoregional and distant progression, and biochemical recurrence; whether these findings apply to high-risk disease remains to be determined.

Key Points: Neoadjuvant Androgen Deprivation and Radiation Therapy

- Neoadjuvant and concurrent AD appears to be appropriate in high-risk

patients undergoing RT.
- Adjuvant AD after RT may benefit those with very high-risk disease.

Adjuvant Androgen Deprivation and Radiation Therapy

Several prospective studies have assessed the role of adjuvant AD after RT and the appropriate duration of such therapy. RTOG 85-31 randomized 977 patients with T3NXM0 or T1–T2N+M0 prostate cancer to RT and either goserelin started during the last week of RT and continued indefinitely, or goserelin started at the time of relapse (i.e., early or late AD). The groups were matched with respect to disease risk characteristics, and fewer than 30% had lymph node involvement. Improved local control and BDFS and metastasis-free survival were noted in the adjuvant AD group at 8 years of follow-up, and this advantage was most prominent with Gleason sum 8 to 10. Overall survival was not statistically different at 5 years (75% vs. 72%) and 8 years (49% vs. 42%). In those patients with high-grade tumors, adjuvant AD improved disease-specific survival (90% vs. 78%) and overall survival (80% vs. 69%) at 5 years.

In the EORTC 22863 study, men undergoing external-beam RT for clinically localized disease (cT1–T2 and grade 3, cT3–T4 and any grade) were randomized to RT alone or the addition of goserelin starting at the beginning of treatment and continuing for 3 years (Bolla et al., 1997). This is the only study to demonstrate an overall survival benefit, with 5-year survival of 79% in the adjuvant AD group and 62% in the RT-alone group ($P = .001$). Disease-free survival was 85% and 48%, respectively, and local control was also improved with AD (97% vs. 79%). Of note, the cohort presented with very high-risk disease, with a median PSA level of 30 ng/mL, and this may account for the relatively low overall survival in the RT-alone cohort.

It does not appear that the method of AD affects the outcome of combined treatment with RT. Granfors et al. (1998) randomized men with cT1–T4pN0–3M0 cancer to either external-beam RT alone or combined orchiectomy and RT; men treated with RT alone received AD at clinical disease progression. At median follow-up of 9.3 years, clinical progression in the RT-alone and RT-plus-AD patients was 61% and 31%, respectively ($P = .005$). Disease-specific mortality was not different; overall mortality was 61% and 38%, respectively ($P = .02$). However, in men with negative lymph nodes, there was no significant difference in survival rates, and the poor survival was primarily caused by metastatic disease at the time of initial treatment.

A meta-analysis of 2742 men treated for clinically localized prostate cancer within RTOG trials from 1975 to 1992 supports the use of adjuvant AD in subsets of patients (Roach et al., 2000). Patients were stratified into four prognostic risk groups, and those in risk group 2 (cT3NX, Gleason 2 to 6; or cT1–T2NX, Gleason 7; or node-positive, Gleason 2 to 6) appeared to have improved disease-specific survival with the addition of short-term (4 months) AD. In further refining the population of patients, limiting the analysis to men with bulky or cT3 disease alone demonstrated a significant survival advantage.

If adjuvant AD is of benefit, the duration of such therapy remains uncertain. RTOG 92-02 supports the use of long-term AD after initial AD with external-beam RT (Hanks et al., 2003). Men with locally advanced tumors (cT2c–T4N0–1M0) received either 4 months of AD (2 months neoadjuvant and 2 months concurrent) with RT or that and 24 additional months of AD. Long-term AD was beneficial in all end points evaluated *except* overall survival, with 5-year rates for both approximately 80%. Subset analysis of men with Gleason sum 8 to 10 noted improved overall survival with 24 months of AD (81%) compared with short-term AD (71%; $P = .044$) and improved disease-specific survival; these findings were confirmed during 10-year follow-up (Horwitz et al., 2008). D'Amico et al. (2004) described 206 men with clinically localized but higher-risk (PSA ≥10 ng/mL, Gleason sum ≥7, cT3) prostate cancer randomized to RT alone (70 Gy) or RT with 6 months of AD. Overall and disease-specific survival rates were improved with AD compared with RT alone. Actuarial 5-year survival and freedom from salvage AD were 88% and 82%, respectively, after early AD and 78% and 57% with RT alone. In conjunction with high-dose RT, 2 years of adjuvant AD was superior to short-term, concurrent AD with respect to biochemical recurrence, overall survival, and metastasis-free survival (Zapatero et al., 2015); the benefit was more pronounced in the high-risk group compared with those with intermediate-risk disease. **Thus a limited period of AD (2 to 4 months) appears to be appropriate for men with intermediate-risk cancers; more prolonged AD may be beneficial for those with high-risk disease characteristics, including high-stage cancers, or men with high pretreatment serum PSA values.**

Other aspects of RT for men with more advanced tumors require clarification, including the dose and extent (i.e., prostate only vs. prostate and pelvis) applied. RTOG 94-13 randomized men with an estimated risk for lymph node metastasis of 15% into one of four arms: (1) whole-pelvis RT plus neoadjuvant and concurrent AD, (2) prostate-only RT plus neoadjuvant and concurrent AD, (3) whole-pelvis RT plus adjuvant AD, and (4) prostate-only RT plus adjuvant AD (Lawton et al., 2007; Roach et al., 2003). Initial analysis suggested improved progression-free survival for whole-pelvis compared with prostate-only RT and no difference for the two types of AD. In comparing the four groups after longer follow-up, however, progression-free survival rates were similar, with significant difference only in overall survival among the groups (*P* = .027). Surprisingly, overall survival was poorer in patients receiving whole-pelvis RT plus adjuvant AD compared with all other cohorts.

The differences in RT dose among the various prior and contemporary studies make comparisons of efficacy difficult because emerging data support doses greater than 72 Gy as being more effective (Cheung et al., 2005; Jacob et al., 2005). In addition, the role of combined external-beam RT and brachytherapy (both permanent and high-dose rate) needs to be better elucidated. Brachytherapy has generally been used to treat patients with lower-risk features. Its use in those with high-risk disease characteristics, often in combination with AD and external-beam RT, has been less well studied. Potters et al. (2005) noted a 63% BDFS in those treated with permanent prostate brachytherapy. A similar outcome was noted with the use of high-dose-rate intensity-modulated brachytherapy with external-beam RT (Demanes et al., 2005). Sylvester et al. (2003) treated men with interstitial permanent brachytherapy combined with moderate-dose (45 Gy) neoadjuvant external-beam RT. In those with high-risk disease (by D'Amico criteria), the 10-year BDFS was 48%; of note, AD was not used. Stock et al. (2004) evaluated a multimodal protocol using neoadjuvant and concomitant AD (9 months total), brachytherapy, and three-dimensional conformal RT in a high-risk cohort. The 5-year BDFS was 86%, with Gleason sum the only variable associated with PSA failure. Excellent local control was also demonstrated, with no patient harboring cancer on the last post-treatment biopsy. The ASCENDE-RT trial randomized 398 men with NCCN high- and intermediate-risk disease to treatment with 12 months of AD, pelvic irradiation to 46 Gy, and either dose-escalated external-beam RT (78 Gy) or low-dose-rate prostate brachytherapy (Morris et al., 2017). Although no difference in overall survival was observed between the two prostate radiation treatment arms, biochemical recurrence was significantly higher in the external-beam RT group (HR 2.04). The 20% estimated difference at 9 years (85% vs. 65%), especially in the high-risk subset, may further increase with longer follow-up given the sharp divergence at 4 years.

Radiation Therapy and Chemotherapy

The role of chemotherapy in conjunction with RT is less well studied than that for surgery and chemotherapy. Khil et al. (1997) administered estramustine and vinblastine concurrently with RT (total 65 to 70 Gy) in men with locally advanced disease. Although clinical control was reasonable at 5 years at 81%, only 48% of patients had a PSA level below 4 ng/mL at this time. Zelefsky et al. (2000) enrolled 27 patients with high-risk disease (Gleason sum ≥8 and PSA >10 ng/mL; Gleason sum 7 and PSA >20 ng/mL; cT3N0M0 and PSA >20 ng/mL; cT4N0M0; cTXN1M0) in a phase II clinical trial of the same agents, with RT at 75.6 Gy. Only a modest increase in grade 2 toxicity was noted, and no late grade 3 or grade 4 toxicities were observed. The 2-year BDFS was 60%. An update reported median time to PSA relapse of 12 months, with 48% of patients receiving no additional therapy, and median time to metastasis had not been reached (Ryan et al., 2004).

An estramustine-based regimen has also been examined with etoposide before and during definitive RT (Ben-Josef et al., 2001). Actuarial disease-free survival and overall survival were 73% and 88%, respectively, at 3 years. Local control as determined by biopsy was 71% at 18 months. A phase I study examined concurrent docetaxel and RT (70.2 Gy) in 22 men (Kumar et al., 2004). The maximal tolerated dose was determined to be 20 mg/m^2, with diarrhea and dysuria the primary toxic effects. All patients were alive at last follow-up, and 77% had continued biochemical response. These promising results support further study of the combined use of RT and chemotherapeutic agents.

RTOG 9902 does not suggest that the addition of adjuvant paclitaxel, estramustine, and etoposide to long-term AD and RT benefits men with high-risk disease (Rosenthal et al., 2015). At median follow-up of 9.2 years, there was no significant difference for all endpoints including overall and disease-specific survival, and biochemical and clinical progression. It should be noted that the trial was closed early as a result of thromboembolic events associated with the chemotherapy arm.

GETUG 12 randomized patients with cT3/T4, Gleason ≥8, PSA ≥ 20 ng/mL, or node-positive disease identified by lymphadenectomy without metastases to prolonged AD alone or combined with docetaxel and estramustine (Fizazi et al., 2015). Nodal disease was present in 29% of the cohort, and local therapy was predominantly RT (87%). The chemotherapy group had better relapse-free survival (62% vs. 50%, HR 0.71) with no increase in toxicity or secondary cancers.

The landmark STAMPEDE trial provides additional evidence that outcomes of RT may be improved with combination systemic therapy. Approximately 50% of enrolled men had high-risk or N+M0 prostate cancer, with most receiving RT for local therapy. The addition of either docetaxel or abiraterone at the time of AD initiation resulted in significant improvements in both overall and failure-free survival (James et al., 2016, 2017). It remains to be determined whether aggressive treatment of the prostate is essential and whether the benefit is primarily limited to those with metastatic spread, rather than locally advanced or regional disease.

Focal Ablative Therapy

Advances in technology have provided methods to ablate prostate tissue while being minimally invasive. There is renewed interest in primary cryoablation, particularly as focal treatment for localized disease and salvage therapy, and high-intensity focused ultrasonography (HIFU) appears promising. The ability to treat local disease within the prostate by these modalities may play a role, even in men with locally advanced disease, most likely in combination with AD or other systemic therapy.

Cryoablation

Several series have been reported regarding primary cryoablation of the prostate and include many men with high-risk disease (Ahmed et al., 2009). Long et al. (2001) reported on 975 men undergoing cryoablation. In this study, 41% were high risk and 24% were stage cT3. At a median follow-up of 24 months, the 5-year actuarial BDFS, defined as PSA less than 1 ng/mL, was 41%. A similar PSA outcome (35%) using the same definition was observed in another group of men with PSA 10 ng/mL or greater and/or Gleason sum 8 or higher undergoing primary cryoablation (Prepelica et al., 2005). However, use of more stringent PSA cutoff values may result in significantly poorer outcomes, with 2-year rates of biochemical failure higher than 80% if thresholds of 0.5 or 0.2 ng/mL are applied (El Hayek et al., 2008). Chin et al. (2008) randomized men with clinical stage T2c–T3 disease to 6 months of AD and either cryoablation or RT at 66 Gy. At a mean follow-up of 37 months, there were no differences in disease-specific (95% to 97%) and overall (87%) survival, but cryoablation was associated with shorter PSA-free survival (28 months vs. 41 months) and higher biochemical failure (87% vs. 53%).

High-Intensity Focused Ultrasonography

The role of HIFU continues to be elucidated, particularly in men with locally advanced prostate cancer. The limited existing data are confounded by frequent omission of risk stratification and common use of AD to reduce prostate size. At 1-year follow-up, 30 men with locally advanced or high-risk disease receiving AD plus HIFU had reasonable local control, with PSA less than 0.3 ng/mL and negative sextant biopsies in 90%; no patient had clinical disease progression (Ficarra et al., 2006). A larger series by Sumitomo et al. (2008) compared men receiving HIFU with and without NAD and without subsequent adjuvant therapy. In the 29% with high-risk cancers (by D'Amico criteria), NAD reduced both positive biopsy rate and biochemical failure. Three-year disease-free survival was independently affected by stage cT2c or higher (HR 2.34) and lack of NAD (HR 2.19) in multivariate analysis. Parallel to studies of RT, outcomes of local treatment using HIFU may be improved when combined with NAD, primarily in men with intermediate- and high-risk disease characteristics.

Androgen Deprivation and Its Timing

The VACURG and MRC trials suggest a benefit to early application of AD in men with locally advanced prostate cancer. The first VACURG study randomized 1050 patients with stage III disease and 853 patients with stage IV disease to placebo, 5 mg of DES, orchiectomy plus placebo, or orchiectomy plus 5 mg of DES. All three AD arms had significantly less progression than the placebo group, but this did not translate into an overall survival benefit. The inability to demonstrate a survival benefit cannot be completely attributed to the increased cardiovascular deaths within the DES groups because survival in the orchiectomy plus placebo group was not significantly different from that in the placebo-alone group. The second VACURG study randomized 1506 men with stage III and stage IV disease to placebo or one of three doses of DES (0.2 mg, 1 mg, 5 mg). DES at 1 mg and 5 mg delayed progression of stage III disease, and patients receiving 1 mg had improved overall survival. However, the 5-mg dose of DES again resulted in increased cardiovascular death. Subsequent analysis suggested that immediate estrogen therapy was most beneficial in patients younger than 75 years with high-grade tumors (Gleason sum 7 to 10). The third VACURG study supported that only a subset of men with prostate cancer benefit from early AD. In men with stage II disease, 5-year survival was 48% with placebo and 75% with 1 mg of DES. **Taken together, the VACURG data provide evidence of benefit for early AD with respect to disease progression and potential survival only in subsets of men with more aggressive disease** (Byar, 1973; Byar and Corle, 1988)**. The studies also clearly show that alternatives to estrogen should be used, given the cardiovascular toxicity associated with higher doses of DES.** The current ability to better monitor disease progression, with use of PSA kinetics and imaging modalities, may improve the outcomes of delayed AD by better determining when institution of AD is necessary.

The MRC also evaluated the issue of early versus delayed AD (orchiectomy or LHRH agonist) in 938 patients with prostate cancer, of whom 501 had locally advanced disease. The majority of deaths (67%) were attributed to prostate cancer. Disease-specific mortality was 55% in the early AD group and 43% in the deferred group ($P = .001$). Overall survival was also improved in the immediate AD arm ($P = .02$). The reduction in prostate cancer deaths was primarily a result of patients with M0 disease. This study also provides important data for comparison to other forms of treatment. Median time to death from prostate cancer (cT3M0) was 90 months, comparing favorably to EORTC 22863, in which median time was not reached after 65.7 months. Similarly, median overall survival in the MRC study was 64 months but not reached in EORTC 22864 (56.7 months of follow-up). Thus the apparent beneficial effects of combined AD and RT may be in part caused by AD alone with uncertain incremental advantage of RT. The results from the Scandinavian Prostate Cancer Group Study 7/Swedish Association for Urological Oncology 3 (SPCG-7/SFUO-3) trial suggest an important role of RT, in addition to AD, in men with locally advanced disease (78% cT3) (Widmark et al., 2009). Men were randomized to either total AD followed by continuous flutamide or endocrine therapy combined with RT. At median follow-up of 7.6 years, both prostate cancer–specific and overall mortality were decreased in the group receiving AD plus RT (RR 0.44 and 0.68, respectively), and PSA recurrence was higher in men receiving AD alone (75%) compared with the RT group (26%). Despite limitations including the unconventional endocrine regimen and open study design, use of RT and potentially other local treatment modalities appears warranted in men with locally advanced prostate cancer. The MRC UK PR07 trial similarly compared AD only with AD and RT; in this study, patients had more advanced disease, AD was accomplished by either continuous LHRH agonist or orchiectomy, and pelvic nodes were treated with RT. The addition of RT to AD improved disease-specific (HR 0.54) and overall (HR 0.77) survival at 7 years (Warde et al., 2011). These findings were confirmed with further follow-up, and death from prostate cancer was significantly reduced by the addition of RT to AD (HR 0.46) (Mason et al., 2015).

Studer et al. (2004) evaluated the timing of AD in a study randomizing 197 asymptomatic men with prostate cancer to either immediate or deferred subcapsular orchiectomy; of note, patients were either unsuitable for or unwilling to undergo surgery or RT. A significant fraction of the cohort had higher-risk features, with clinical stage T3 or higher in 67% and median serum PSA level above 46 ng/mL. Of the 92 men in the deferred treatment arm, 42% never required AD; the majority died of causes unrelated to prostate cancer. The median time to deferred AD was 3.2 years, the most common indication being skeletal metastases (45%) and ureteral obstruction (25%). Although overall survival was not different between the immediate and deferred groups (P = .96), a trend toward improved disease-specific survival was noted in those men receiving immediate AD, with an HR for death from prostate cancer of 0.63 (P =

.09).

To minimize adverse impact on quality of life, antiandrogen therapy alone has been proposed as an alternative to orchiectomy or LHRH agonists. Iversen et al. (2004) reported on the effects of 150 mg of bicalutamide in men with localized or locally advanced prostate cancer, the majority of whom were untreated initially (81%). At median 5.3 years of follow-up, survival in those with locally advanced disease was improved with bicalutamide compared with placebo (HR 0.68). Overall, risk for disease progression was reduced by 43%, with the greatest benefit in locally advanced tumors (HR 0.4). The combined analysis of the three Early Prostate Cancer bicalutamide trials (N = 8113) confirmed improved progression-free survival in the bicalutamide group (Wirth et al., 2004a). Overall survival was not different between the treatment and placebo arms in each trial, but men with locally advanced disease receiving bicalutamide alone (i.e., no surgery or RT) appeared to have improved survival. Although apparently promising in men with high-risk tumors, bicalutamide at 150 mg must be approached cautiously, both in men deferring local therapy and after definitive treatment. In analysis of the Early Prostate Cancer data (median follow-up of 5.4 years), men with localized prostate cancer receiving bicalutamide as primary therapy had an increased risk for death (HR 1.23, 95% CI, 1.00 to 1.50) compared with surveillance alone. Immediate high-dose bicalutamide is not currently appropriate in men with low risk for disease progression, and potentially adverse effects should be sought in higher-risk patients with extended follow-up.

Wirth et al. (2004b) tested adjuvant flutamide (750 mg) after radical prostatectomy in men with pT3–T4N0 disease. Recurrence-free survival, defined as a single PSA value above 5 ng/mL or two PSA values above 2 ng/mL, was improved with flutamide (HR 0.51) at median follow-up of 6.1 years; however, overall survival was comparable (HR 1.04). Significant toxicity was associated with flutamide and accounted for nearly one-half of withdrawals from the treatment arm.

Key Points: Androgen Deprivation

- Early AD may improve survival.
- Alternative methods of androgen manipulation (antiandrogen, intermittent) remain investigational.

Intermittent Androgen Deprivation

Another approach to minimizing AD-related morbidity is the intermittent application of androgen suppression. Forty-nine patients (28 with cT3–T4N0M0 disease) were treated with total AD until the PSA level was less than 4.0 ng/mL between 24 and 32 weeks, after which treatment was withheld after 36 weeks (Sato et al., 2004). PSA level was then monitored and treatment was recommended when the PSA level reached either pretreatment level (when it was <15 ng/mL) or 15 ng/mL (when the initial PSA level was higher than that). During median follow-up of 126.1 weeks, mean time off treatment during cycles 1, 2, and 3 was 46.1, 36.9, and 23.3 weeks, respectively. No symptomatic or clinical disease was reported in the nonmetastatic subgroup, and PSA failure was observed in 3 (11%) of these patients, with all patients alive at last evaluation. The optimal timing of intermittent AD for reduction of patient morbidity and disease-specific end points remains to be determined, particularly in light of data from the trial of intermittent versus continuous AD in men with metastatic, hormone-sensitive prostate cancer (Hussain et al., 2013).

Quality of Life

The early institution of AD in men with prostate cancer, whether the cancer is localized or locally advanced, must be balanced against the known side effects and long-term morbidity. Only recently has the impact of AD on bone events, cognitive function, and quality of life been appreciated and reported. In comparing bicalutamide (150 mg) and castration with locally advanced but nonmetastatic disease, both sexual interest and physical capacity were better with bicalutamide monotherapy (Iversen et al., 2000). Although hot flashes were more common with castration, a trend toward reduced quality of life was associated with bicalutamide, including higher incidence of gynecomastia, breast pain, and asthenia. In the study of intermittent AD from Sato et al. (2004), many quality-of-life domains were improved during off-treatment cycles, including potency and social and family well-being.

The multimodal approach with AD and RT may increase the relative toxicity compared with each intervention alone. Schultheiss et al. (1997) reported that NAD was correlated with later gastrointestinal and genitourinary (grade 2 or higher) morbidity. Another study found that adjuvant AD after RT predicted for late grade 2 to grade 4 rectal toxicity (Sanguineti et al., 2002). Within RTOG 86-

10, potency after RT with or without AD was similar at 81% and 74%, respectively. Chen et al. (2001) also found that the addition of AD did not further contribute to decline in sexual function after RT. Zelefsky et al. (1999) evaluated predictors of late toxicity in men treated with three-dimensional conformal radiotherapy. Although the 5-year actuarial likelihood of gastrointestinal and urinary toxicities was low (<10% overall), use of NAD was an independent predictor ($P = .01$) of post-treatment erectile dysfunction. The incidence of rectal morbidity and sexual dysfunction may be related to duration of AD longer than 6 or 9 months.

The benefits of adjuvant AD plus RT for locally advanced prostate cancer, both short and long term, appeared to outweigh the associated side effects in a number-needed-to-treat analysis (Jani et al., 2003). A model that compared treatment options while incorporating benefit and complications was constructed, and data from randomized trials of RT with or without AD for cT2c–T4N0–1 disease were input into the calculation. Even considering the increased incidence of side effects of long-term AD, this approach appeared to be better than short-term AD for virtually all end points evaluated.

Given concerns regarding AD and impact on body mass index, lipid profile, diabetes, and cardiovascular disease, Efstathiou et al. (2009) assessed the relationship between AD and cardiovascular events within RTOG 85-31. Adjuvant AD (median duration 4.2 years) was not associated with increased cardiovascular mortality. Additional evidence from RTOG 86-10 suggests that short-term NAD also does not increase the risk for fatal cardiac events.

Management of Delayed Sequelae

The direct comparison of prostatectomy and RT in the treatment of locally advanced prostate cancer is challenging and primarily based on historical studies. Even with the addition of neoadjuvant and adjuvant systemic therapy, leaving the prostate gland in situ poses potential problems. First, effective local control of some high-risk cancers may influence survival. Second, local recurrence may lead to the need for additional treatment of the prostate. At 10 years, local recurrence rates after RT for cT3 or stage C disease range from 24% to 74%. Holzman et al. (1991) reported that 36% of patients required transurethral resection of the prostate because of urinary obstruction after RT alone, without AD. Other morbidities included hydronephrosis (20%) and incontinence (13%). An older report also demonstrated significant local complications of stage C prostate cancer with nonextirpative interventions—infection (80%), bladder outlet obstruction (75%), gross hematuria (45%), and ureteral obstruction (40%) (Tomlinson et al., 1977). Systemic therapy in the form of AD may not prevent local progression or reduce the need for palliative intervention. Despite orchiectomy for bladder outlet obstruction, 31% of men with locally advanced disease required transurethral prostate resection because of persistent voiding dysfunction after 60 days. Similarly, in 277 patients with cT2–T4 disease randomized to orchiectomy, RT, or both, rates of local disease control were comparable (Fellows et al., 1992). Studer et al. (2004) demonstrated that AD alone, whether it is instituted early or late, does not prevent local morbidity. More than one-half of the men in their study required transurethral resection of the prostate. In addition, delayed institution of AD was necessary because of ureteral obstruction (25%), anticipation of local complications (10%), and rectal infiltration (4%).

Quality of life is an increasingly important end point for prostate cancer. However, the impact of untreated local tumor progression or the various treatment modalities for locally advanced disease on quality-of-life outcomes is poorly characterized. Rosenfeld et al. (2004) examined the relationship between cancer stage and quality of life in 341 ambulatory men with prostate cancer. Instruments used included the Functional Assessment of Cancer Therapy (FACT), the urinary function subscale of the UCLA Prostate Cancer Index, and the Hospital Anxiety and Depression Scale (HADS). The stage of prostate cancer was significantly associated with most FACT subscales—increasing stage was negatively correlated with nearly every FACT subscale score; the observation persisted in multivariate models, accounting for covariables such as comorbidity and time since diagnosis. Interestingly, stage was more strongly associated with physical domains of health-related quality of life, and there was no association with psychological symptoms as measured by HADS.

Berg et al. (2007) treated high-risk patients with RT monotherapy and characterized quality of life using validated instruments. Although mean scores for bowel function were similar to those for a normative control population, bowel bother and diarrhea were greater after RT. Patients who had clinical progression or required AD reported poorer sexual, urinary, and social function and more sleeping problems and exhibited great declines in all domains over time. Data from CaPSURE also suggest that men with high-risk cancer are likely to suffer negative effects beyond cancer outcomes (Wu et al., 2008). Use of AD with both surgery and RT was associated with a loss of sexual function that improved within 9 months, whereas the combination of external-beam RT and brachytherapy resulted in continuous worsening of urinary function and bother.

Additional evidence from SWOG 8794 supports an adverse impact of multimodal therapy on quality of life (Moinpour et al., 2008). Men receiving adjuvant RT reported poorer bowel and urinary function, but not erectile function, compared with surgery alone. Although symptom distress was significantly worse for the adjuvant RT group, likely correlating with bowel and urinary problems, there were no differences in other general measures of health-related quality of life, whereas global health-related quality of life was initially poorer but continuously improved over time after adjuvant RT.

Clinical Trials

Given that outcomes of therapy are not optimal for those men with high-risk disease features, patients who present with such cancers should be considered for enrollment in novel clinical trials (http://clinicaltrials.gov/). SPCG 15 (NCT 02102477) plans to randomize 1200 men with newly diagnosed high-risk prostate cancer (cT3N0M0 and Gleason 4 and PSA <100 ng/mL) to either prostatectomy or RT + AD, with disease-specific survival as the primary endpoint. Table 159.11 summarizes phase III clinical trials for high-risk or locally advanced prostate cancer; some of these trials have completed accrual, and others are ongoing. The resulting data should answer some of the current questions regarding the optimal type and timing of traditional combination treatment, and the role of chemotherapy, in men with locally advanced and high-risk prostate cancer.

TABLE 159.11

Current and Pending Phase III Clinical Trials in Locally Advanced/High-Risk Prostate Cancer

STUDY	ELIGIBILITY CRITERIA	TREATMENTS
RADICAL PROSTATECTOMY		
AUO AP 55/09 (SEAL)	Gleason 7–10 or PSA >10 ng/mL surgery + limited vs. extended pelvic lymphadenectomy	
NEOADJUVANT		
CALGB 90203[a]	Clinically localized, ≤60% 5-yr disease free, Gleason 8–10	Surgery alone vs. estramustine/docetaxel
ADJUVANT		
SWOG 9921[a]	Gleason 8–10, pT3b–4, PSA >20 ng/mL, N1, Gleason 7 and + margin	AD (2 yr) vs. AD + mitoxantrone/prednisone
VA Study 553[b]	pT3b–4, pT3a and Gleason ≥7, pT2 and Gleason 8–10 and + margin, PSA >20 ng/mL	Surveillance vs. docetaxel/prednisone
SPCG 12[b]	pT3a and Gleason ≥4+3, pT2 and + margin and Gleason ≥4+3, pT3b and Gleason ≥7	Surveillance vs. docetaxel
NCT 00667069	>pT2 or R1 N0/x and PSA ≤0.1 ng/mL	Immediate vs. delayed RT + triptorelin

(GETUG-17)		
MRC PR 10[a] (RADICALS)	After radical prostatectomy with PSA ≤0.2 ng/mL: pT3–4, Gleason 7–10, preoperative PSA ≥10 ng/mL, + margin	Immediate vs. delayed RT RT vs. RT + 6 mo AD vs. RT + 24 mo AD
NCT 00860652 (RAVES)	After radical prostatectomy with PSA ≤0.1 ng/mL and + margin or pT3a or pT3b	Immediate vs. delayed RT
NCT 01442246 (AFU-GETUG 20)	After radical prostatectomy with PSA <0.1 ng/mL and pT3b or Gleason >7 or Gleason 7 with tertiary 5	Surveillance vs. 24 mo AD
EXTERNAL-BEAM RADIATION THERAPY		
RTOG 0924	Gleason 7–10 and cT1c–2b and PSA <50 ng/mL, Gleason 6 and cT2c–4 or >50% biopsies and PSA <50 ng/mL, Gleason 6 and cT1c–2b and PSA >20 ng/mL	NAD + prostate/seminal vesicle RT + RT boost vs. NAD + whole-pelvic RT + RT boost
NCT 00967863[a] (GETUG-AFU 18)	cT3–T4 or PSA ≥20 ng/mL or Gleason ≥8–10 and N0	AD (3 yr) + 70 Gy vs. 80 Gy RT
NCT 01952223 (PEACE 2)	2 or more of: cT3–T4, Gleason ≥8, PSA ≥20 ng/mL	Assessing addition of pelvic RT, cabazitaxel to standard prostate RT + 3 yrs AD
NEOADJUVANT		
CAN-NCIC-PR12	≥T3a, Gleason ≥8, PSA >20 ng/mL	NAD + docetaxel vs. NAD
ADJUVANT		
NCT 116142	cT1–T2a and PSA <10 ng/mL or Gleason ≥4+3 or PSA velocity >2 ng/mL/yr, cT2c–4 and tertiary Gleason 5 or T3b or Gleason ≥3+4 with ≥50% cores positive	AD vs. AD + docetaxel
RTOG 0521	Gleason ≥9 and PSA ≤150 ng/mL, Gleason 8 and PSA <20 ng/mL and ≥cT2, Gleason 7 or 8 and PSA 20–150 ng/mL	AD vs. AD + docetaxel/prednisone
RTOG 1115	Gleason ≥9 and PSA ≤150 ng/mL and any T stage, Gleason 8 and PSA <20 ng/mL and ≥T2, Gleason 8 and PSA 20–150 ng/mL and any T stage, Gleason 7 and PSA 20–150 ng/mL and any T stage	AD (24 mo) + dose-escalated RT vs. AD (24 mo) + TAK-700 + dose-escalated RT

SPCG 13[a]	cT2 and Gleason 4+3 and PSA 10–70 ng/mL, cT2 and Gleason 8–10 and PSA <70 ng/mL, cT3	AD vs. AD + docetaxel
ANDROGEN DEPRIVATION		
NCT 223171 (PCS IV)	cT3–T4 or Gleason 8–10 or PSA >20 ng/mL	RT + 36 vs. 18 months AD

[a] Fully accrued.

[b] Abstract presented.

AD, androgen deprivation; *Gy,* gray; *mo,* month; *NAD,* neoadjuvant androgen deprivation; *PSA,* prostate-specific antigen; *RT,* radiation therapy; *yr,* year.

Management Strategies for Biochemical Recurrence of Prostate Cancer

---

Eugene K. Lee MD, J. Brantley Thrasher MD, FACS

Radical Prostatectomy

Definition of Biochemical Recurrence After Radical Prostatectomy

Radical prostatectomy is one of the most common treatment modalities for localized prostate cancer, and despite advances in surgical technique and careful patient selection, approximately 25% to 41% of men will develop prostate-specific antigen (PSA) recurrence 10 years after surgery (Amling et al., 2000; Hull et al., 2002; Roehl et al., 2004). Additionally, since the U.S. Preventive Services Task Force grade D recommendation for PSA screening in 2012 (grade C on 2017 updated draft), there has been a decrease in overall screening and a "reverse" stage migration for more aggressive disease (Fleshner et al., 2017). When evaluating men with high-risk prostate cancer, the risk for PSA recurrence can be as high as 60% at 5 years (Beauval et al., 2016).

It is clear that not all men with a detectable PSA after surgery are destined to clinical progression defined as development of metastatic disease, need for second-line treatment, or death from prostate cancer. In fact, some men will have a detectable PSA postprostatectomy that plateaus and does not subsequently rise. In fact, Spahn et al. (2017) recently reported in their cohort of 622 patients with intermediate- and high-risk disease that only 52% went on to have clinical failure (14% local recurrence only, 9% lymph node metastasis, 24% distant metastasis) at a median time of 9.9 years, 4.9 years, and 5.6 years, respectively.

Several hypotheses exist as to why detectable PSAs do not always translate to clinically relevant disease. First, benign disease remains in the prostatic bed (often the rationale for detectable PSA after radiation therapy). Second, PSA is produced at low levels by cells of nonprostatic origin (Diamandis and Yu, 1995). Third, PSA elevation is a result of residual low-grade prostate cancer destined to follow an indolent course (Amling et al., 2001).

In the prostate cancer literature, specifically after radical prostatectomy, there are greater than 50 separate definitions of biochemical recurrence (Cookson et al., 2007; Moul et al., 1996; Zincke et al., 1994). A standard definition of PSA recurrence is necessary to accurately predict for progression to clinically meaningful end points. This must be tempered by the need for this same definition to identify patients at low enough PSA levels (disease burden) to intervene with second-line therapies at a point in the disease course that will prevent further risk for advanced prostate cancer.

Stephenson et al. (2006a) reviewed the Memorial Sloan Kettering experience of 3125 patients who underwent radical prostatectomy. Using a goodness-of-fit (R^2) statistic, they examined 10 candidate definitions and determined that a PSA of at least 0.4 ng/mL followed by subsequent increase was the best fit for metastatic progression, high predictability for secondary therapy, further PSA progression, and rapid doubling time. Furthermore, Amling et al. (2001) also determined significance in using a definition of PSA 0.4 ng/mL or greater. Lost in a "standard" definition of PSA recurrence is clinical progression risk and how it relates to different definitions of failure. For example, a PSA of 0.1 ng/mL may mean a different clinical outcome in a patient who had a radical prostatectomy 8 years prior with pathologic Gleason 6 disease versus a patient who had surgery 6 months prior for high-volume Gleason 9 prostate cancer with T3b disease. Mir et al. (2014) addressed this issue by examining 14 definitions of biochemical recurrence and how they relate to the probability of subsequent rise in PSA, usage of secondary treatment, or clinical progression. In the entire cohort, a single detectable PSA, even at low levels (≤0.1 ng/mL), was associated with a subsequent rise in 30% to 55% of patients. In patients with high-risk features, a detectable PSA was associated with a PSA progression probability of 73% to 88% compared with only 18% to 25% in patients with low-risk features. The optimal definition for patients with a 5-year progression-free probability of less than 50% (high-risk patients) was a single PSA greater than or equal to 0.05 ng/mL, and the ideal cut point in those with a progression-free probability greater than 90% (low-risk patients) was a PSA greater than or equal to 0.4 ng/mL. These data can assist clinicians in counseling patients on the need for appropriate salvage therapies while sparing those at low risk for ever developing metastasis (Morgan et al., 2014).

Because of the wide variation in definition of biochemical recurrence, the American Urological Association (AUA) Guidelines Panel for Localized Prostate Cancer released their recommendations for reporting PSA recurrence in 2007. Their goals in a unifying definition was to determine an early marker of treatment failure in advance of clinical progression, use a low enough value to allow for patients to be candidates for early salvage therapy, and for a standard definition to be used as comparisons among different patient series. **The AUA Guidelines Panel ultimately defined PSA recurrence as a value of greater than or equal to 0.2 ng/mL with a second confirmatory laboratory value** (Cookson et al., 2007). This has also been adopted by the European Guidelines on Prostate Cancer (Cornford et al., 2017).

The Prediction of Biochemical Recurrence Postprostatectomy

It is clear that all clinically relevant recurrences are predicted by a rise in PSA, and identifying patients who will have biochemical recurrence is important in terms of counseling, identifying patients needing secondary therapy, and potentially treating with neoadjuvant treatments on clinical trials. Using data from large operative series in men with prostate cancer, it has become clear that clinical factors can be used to predict for biochemical failure. Roehl et al. (2004) determined that the most important factors for predicting biochemical recurrence were pretreatment PSA, clinical stage, Gleason sum, pathologic stage, and era in which the radical prostatectomy was performed. Others have confirmed the importance of Gleason score, clinical stage, PSA before surgery, and pathologic stage as the most significant covariates for predicting biochemical recurrence (Han et al., 2003).

Achieving negative surgical margins is critical, as this is an important predictor of biochemical failure (Stephenson et al., 2005). Compared with a negative margin, men with positive margins in pT2 prostate cancer had a 12% increased risk for biochemical recurrence, and in pT3a and pT3b, the increased risk was 12% and 18%, respectively (Budaus et al., 2010). In fact, in this cohort of patients, those with pT3a and negative margins had a lower risk for biochemical recurrence than patients with pT2 cancer and positive margins (Budaus et al., 2010). The length of positive margin has also been predictive of biochemical recurrence, as those with margins greater than 1 mm have a statistically significant increased risk for biochemical failure (Shikanov et al., 2009). Others have found that multiple positive margins and location of margin may be significant (Sofer et al., 2002; Stephenson et al., 2005). Recently, it has been shown that a Gleason score greater than or equal to 4 at the location of positive margin was predictive of biochemical failure (Chapin et al., 2018). Taken together, these data emphasize the importance of meticulous surgical dissection.

In the age of evidence-based medicine and data-driven decisions, it is critical to utilize as much objective information as possible. Using the parameters of clinical stage, serum PSA, Gleason score, and systematic biopsy results, Stephenson et al. (2006b) created a prognostic tool with a concordance index of

0.76 to 0.79 for predicting disease progression defined as serum PSA value of 0.4 ng/mL or greater and confirmed with a higher value, secondary therapy, clinical recurrence, or positive lymph nodes on frozen section during radical prostatectomy. Postoperatively, a similar tool using PSA, Gleason score, presence of extracapsular extension, seminal vesicle invasion, lymph node involvement, margin status, and adjuvant radiation can predict 10-year biochemical recurrence survival with a concordance index of 0.79 to 0.81 (Stephenson et al., 2006b). One important modification of this tool is that it calculates the 10-year progression-free probability based on the current disease-free interval already achieved. Nomograms have become popularized and are easily accessible and frequently used in patient counseling. The most commonly used prostate cancer nomograms accessible on-line are demonstrated in Table 160.1.

Recently, magnetic resonance imaging (MRI) has become increasingly utilized in the diagnosis and treatment planning of patients with prostate cancer. Tan et al. (2018) reported that MRI tumor volume, Gleason score, stage, and margin status were all significant predictors of biochemical recurrence. Additionally, prostate health index (PHI) derived from total PSA, free PSA, and [–2] proPSA has been demonstrated to predict for biochemical recurrence in men undergoing radical prostatectomy (Maxeiner et al., 2017). Other groups have identified nonpathologic factors including ethnicity and obesity as predictors of biochemical recurrence after radical prostatectomy, and others continue to look at genetic and molecular markers of disease such as miRNA and genetic risk scores (Grossfeld et al., 2003; Maj-Hes et al., 2017; Oh et al., 2017; Pashaei et al., 2017). Clearly, the utilization of noninvasive and nonpathologic markers of biochemical failure is important as we move forward with improving patient counseling and decision making for treatment.

Natural History of Biochemical Recurrence Postprostatectomy

Recurrence of PSA normally precedes clinically meaningful events in an extremely protracted and variable manner. In the seminal article describing the natural history of biochemical recurrence after radical prostatectomy, Pound et al. determined that the median actuarial time from biochemical recurrence to metastasis was 8 years (Pound et al., 1999). Furthermore, the median actuarial time to death was 5 years, although this was dependent on the time from biochemical recurrence to metastasis, as patients who developed metastatic disease early had decreased median survival (Pound et al., 1999). In their initial analysis, they determined that the risk for metastasis was dependent on time to biochemical recurrence, Gleason score, and PSA doubling time. In a recent update, metastasis-free survival was 10 years, potentially reflecting improvements in patient selection and management (Antonarakis et al., 2012).

The majority of men who experience biochemical recurrence after radical prostatectomy will not succumb to disease. In fact, even in patients with documented intermediate and high-risk prostate cancer, approximately 50% of patients will not have clinical failure after a median follow-up of 9.4 years. Of the patients with clinical failure, the 5-year disease-specific survival is 90% with local recurrence only, 70% with lymph node disease, and 47% with metastases (Spahn et al., 2017). Risk factors for aggressive progression to clinically relevant disease and death are extremely important for patient counseling, clinical trials, and for early implementation of salvage therapies. Using an established nomogram for prostate cancer recurrence (Kattan et al., 1998), Stephenson et al. (2009) demonstrated that 15-year disease-specific mortality was 5% in the most favorable quartile of PSA recurrence, and patients in the least favorable 5-year PSA progression-free probability quartile had a 15-year disease-specific mortality of 38%. Further, it is important to note that evaluation of PSA after prostatectomy should occur indefinitely as up to 27% of men will recur after 5 years, and these patients are still at risk for clinical progression (Ward et al., 2003).

Ultrasensitive Prostate-Specific Antigen

Traditionally, the lower limits of PSA detection have been in the range of less than 0.1 and 0.2 ng/mL. In the early 1990s, ultrasensitive PSA (uPSA) testing was first introduced and has brought about increased sensitivity but also controversy. It is thought that early second-line treatment in patients destined for clinical failure portends improved survival. However, this is tempered by the risk for overtreating those patients who may never experience clinical failure despite continuous detectable values of extremely low PSA. Hong et al. (2010) demonstrated the utility of the uPSA in predicting biochemical recurrence defined as two consecutive rises in PSA of 0.2 ng/mL or greater. On multivariable analysis, they found that an undetectable uPSA along with preoperative PSA level, pathologic stage, and pathologic Gleason score were all significant predictors of biochemical failure (Hong et al., 2010). Patients with a nadir PSA less than 0.001 had a 3-year biochemical recurrence-free survival of 95.5% compared with 41.5% for those with a nadir PSA greater than or equal to 0.05 (Hong et al., 2010). These findings were confirmed by Shen et al. (2005), who determined PSA relapse (two consecutive PSA ≥0.1 ng/mL) in those with a PSA nadir less than 0.01 was 4% compared with 89% for those with nadir of 0.04 or greater.

Ultrasensitive PSA has demonstrated clinical utility in several scenarios. For instance, patients with undetectable uPSA at 2 years have been found to be unlikely to develop PSA doubling time less than 9 months (defined as a high-risk recurrence) after biochemical failure (Chang et al., 2010). In fact, for every month without a detectable uPSA, the odds of high-risk recurrence were decreased by 4% (Chang et al., 2010). Furthermore, uPSA value at 3 years after radical prostatectomy is also predictive of eventual biochemical failure as patients with a PSA between 0.04 and 0.1 have a 10.8 times greater likelihood of developing eventual biochemical recurrence compared with those with a PSA less than or equal to 0.04 (Malik et al., 2011). This is clinically relevant as patients who are free of disease at the 3-year mark can be counseled about their low-probability of ever developing clinically relevant recurrence, which may ease some anxiety. Even after controlling for risk factors, ultrasensitive PSA nadir seems to be effective in predicting biochemical recurrence. Patients with pathologic T3 prostate cancer with undetectable ultrasensitive PSA have a 5-year biochemical recurrence–free survival of 78% compared with 40% for those who have a detectable ultrasensitive PSA (Eisenberg et al., 2010). Interestingly, in patients with low-risk disease, the difference between patients with undetectable versus detectable ultrasensitive PSA was only 91% versus 89%, respectively, arguing that perhaps the significance of testing may lie in patients with intermediate- and high-risk cancer (Eisenberg et al., 2010).

Recently, the group from Johns Hopkins evaluated banked serum samples using an ultrasensitive PSA assay in men who underwent radical prostatectomy and had undetectable traditional PSA with a cutoff of 0.1 ng/mL. They identified a significant cutoff using a threshold uPSA of 0.01, whereas those with levels below 0.01 had a median biochemical recurrence–free survival of 15.2 years versus 10 years for those with a uPSA of 0.01 or greater (Skove et al., 2017). Similarly, Freedland et al. recently published their results from the SEARCH database identifying that nadir uPSA 1 to 6 months after radical prostatectomy was predictive of eventual biochemical failure. Interestingly, 53% of patients with detectable uPSA at 1 to 3 months had lower values on repeated testing at 3 to 6 months (Skove et al., 2017).

Imaging in Patients With Biochemical Recurrence After Radical Prostatectomy

Patients who experience biochemical recurrence after definitive radical prostatectomy are at risk for both local recurrence and/or distant failure. Identifying patients with local failure only is critical to initiate salvage therapies while sparing those with distant metastatic disease the burden of local salvage therapy. Traditionally, imaging techniques have been limited in the diagnosis of recurrence when PSA levels have been low. For instance, the routine usage of bone scans in patients with PSA levels less than 10 ng/mL is of limited value as only 4% will demonstrate a positive scan (Dotan et al., 2005). Similarly, traditional computed tomography (CT) is also unlikely to be positive in patients with PSA levels less than 10 ng/mL (Okotie et al., 2004). Conversely, transrectal ultrasonography (TRUS) has demonstrated reasonable sensitivity at low PSA levels, especially with masses at the vesicourethral anastomosis. Scattoni et al. (2003) demonstrated that TRUS followed by biopsy was positive in 45% of patients with a PSA less than or equal to 0.5 ng/mL and had 100% sensitivity in patients with a PSA greater than or equal to 2.0 ng/mL. Clearly, the ability to identify the sites of recurrences at low levels of PSA are necessary for planning of secondary treatments.

Indium In 111 capromab pendetide scanning (ProstaScint; Cytogen, Princeton, NJ) incorporates an immunoglobulin G monoclonal antibody that binds to prostate-specific membrane antigen (PSMA). Its usage in patients with biochemical recurrence has been limited as sensitivities and specificities are approximately 60% to 70% (Apolo et al., 2008). Further limiting the clinical adoption of ProstaScint is that the monoclonal antibody has been found to bind to intracellular domains only exposed at apoptosis or necrosis (Troyer et al., 1997). Newer modalities including ^{68}Ga-PSMA positron emission tomography/computed tomography (PET/CT) have shown promise, as the level of detection seems to be lower than in other modalities. Detection rates as high as 65% (for PSA value 0.2 to <0.5 ng/mL), 85.7% (for 0.5 to <1), 85.7% (for 1 to <2), and 100% (for ≥2) have been demonstrated in patients with biochemical recurrence after radical prostatectomy (Grubmüller et al., 2018). Further, in a study of 129 patients with primary prostate cancer, PSA relapse, and persistent disease after prostatectomy, the detection rate was 33.3% at a PSA less than or equal to 0.2 ng/mL, 41.2% at a PSA of 0.21 to 0.5 ng/mL, and 69.2% at a PSA of 0.51 to 1.0 ng/mL. The authors conclude that its ability to identify both presence and location of recurrence can assist in decision making, both with primary and salvage radiation (Schmidt-Hegemann et al., 2017).

Although the usage of ^{18}F-fluoro-2-deoxy-D-glucose (FDG) has been limited by low sensitivity secondary to modest glucose consumption in prostate cancer cells, similar uptake in benign tissue or postoperative scar, and high urinary excretion limiting anatomic delineation, radiotracers such as acetate, choline, and fluorocholine have demonstrated promise (Martino et al., 2011). In fact, the U.S. Food and Drug Administration (FDA) recently approved choline PET for the detection of prostate cancer recurrence, which has demonstrated improvement over FDG PET scans (Picchio et al., 2003). Two radiotracers for choline have been studied with similar results; however, ^{11}C-choline has the advantage of low urinary excretion and quality pelvic imaging. Conversely, ^{18}F-choline demonstrates higher urinary excretion but has a longer half-life, which makes it suitable for centers without a cyclotron (Picchio et al., 2011). The validity of choline PET has been seen at PSA levels less than 2.5 ng/mL as up to 90% of patients will demonstrate positive scans with a specificity of 50% (Rinnab et al., 2007). Similarly, approximately 50% of patients with PSA less than 5.0 ng/mL were found to have a positive focus using ^{18}F-fluorocholine PET/CT. One study has shown the sensitivity and specificity of choline PET to be as high as 98% and 99%, respectively, for bone metastasis (Kitajima et al., 2017). Unfortunately, PET scan with choline may be limited in patients with very low levels of PSA recurrence as only one-half will be positive in patients with PSA less than 1.0 ng/mL (Vees et al., 2007). Another study demonstrated positive scans in only 5% of patients with PSA less than 1.0 ng/mL and 15% of patients with PSA 1.0 to 2.0 ng/mL (Giovacchini et al., 2010). More recently, in 50 patients with biochemical recurrence after prostatectomy or radiation therapy, at PSA levels below 1 ng/mL, 21 (42%) were found to have abnormal ^{11}C-choline PET/CT scans. Tumor recurrence was confirmed in 7/21. In the 29 patients without evidence of positive ^{11}C-choline PET/CT, 2 patients were documented to have a recurrence at 30 months (Gómez-de la Fuente et al., 2018). Contributing to the lack of specificity for choline PET scan may be the findings of uptake in other physiologic conditions including inflammation, as evidenced in a large Italian study of 1000 prostate cancer patients who underwent PET/CT with ^{18}F-choline (Calabria et al., 2017). Current usage of choline PET scan in prostate cancer recurrence is limited.

^{11}C-acetate PET scans are another modality that is gaining favor in the evaluation of recurrent PSA after radical prostatectomy, with a sensitivity as high as 75% in 20 men with a median PSA level of 2.0 ng/mL (Sandblom et al., 2006). Almeida et al. (2012) found an 85% overall detection rate of recurrent or metastatic disease using ^{11}C-acetate PET/CT. Patients with PSA values of 0.4 to 1.0 ng/mL had a detection rate of 73%, and patients with PSA greater than 2.0 ng/mL had a detection rate of 93%. In an update of their series, the authors found positive ^{11}C-acetate PET/CT scans in 637/721 (88%) of patients with biochemical recurrence after radical prostatectomy or radiotherapy. They determined the ideal cut point PSA of 1.09 ng/mL where sensitivity of the scan reached 80% (Fig. 160.1). Additionally, using a PSA doubling time less than 3.8 months, the sensitivity was 85% for a positive scan (Almeida et al., 2017). However, Esch et al. (2017) report the limited utility at low levels of PSA value to be a barrier for usage and question its value in guiding local treatment. More recently, ^{18}F-NaF PET/CT has shown improved sensitivity over traditional bone scans for identifying bone metastasis, and further studies will define its role in usage in the setting of biochemical recurrence (Beheshti et al., 2016).

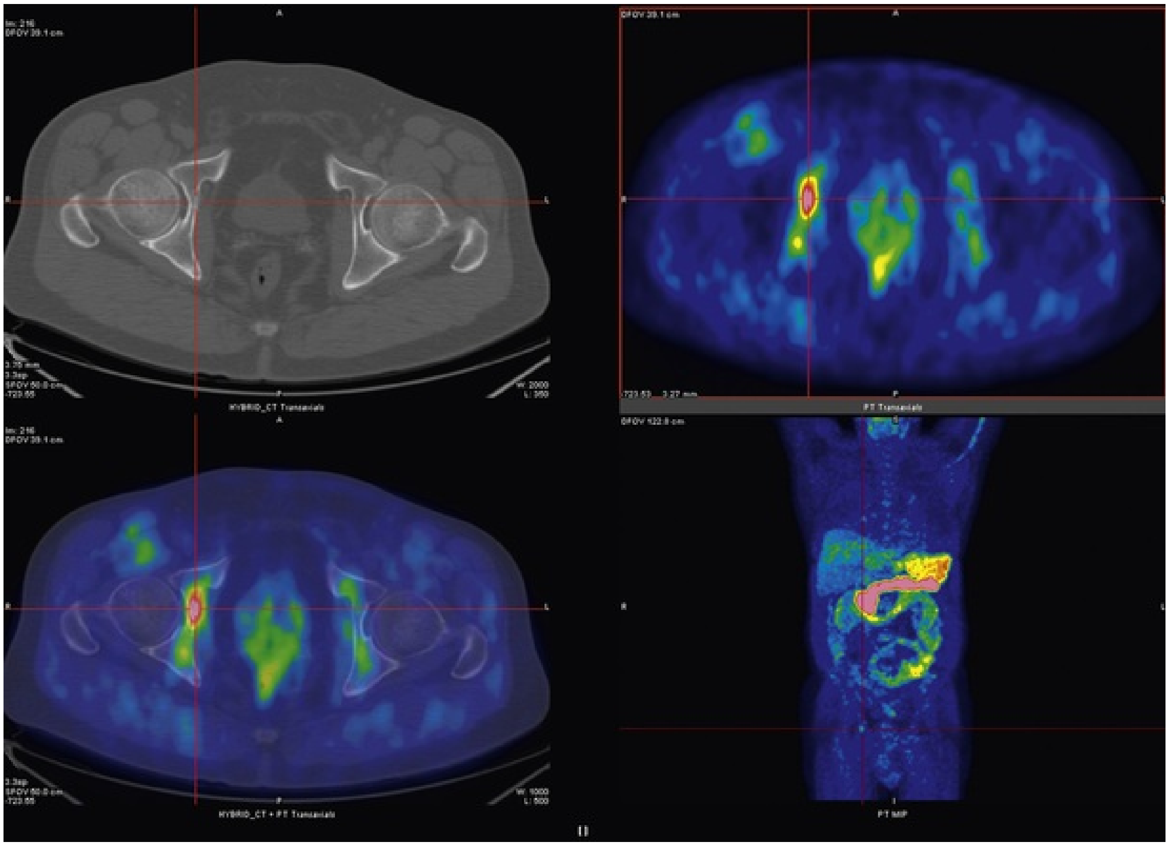

FIG. 160.1 ^{11}C-acetate positron emission tomography scan in biochemical recurrence.

In the evaluation of newer modalities of imaging, tissue correlation with positive scans should be considered the gold standard. When examining ^{68}Ga-PSMA PET/CT, there are very few studies that use histology as the standard reference. In one such study of 42 patients, the authors took a lesional approach to evaluation and demonstrated a sensitivity of 76.6%, specificity of 100%, positive predictive value of 100%, and negative predictive value of 91.4% (Afshar-Oromieh et al., 2015). Similarly, when using tissue or strict clinical definition of recurrence, the detection rate on a recently performed meta-analysis was 62% for choline PET/CT (Fanti et al., 2016). Although historical studies of ^{11}C-acetate PET scans demonstrate positive correlation as low as 40%, more recent reports demonstrate positive predictive values as high as 91% using tissue confirmation (Almeida et al., 2017; Esch et al., 2017; Sandblom et al., 2006). Clearly, further studies utilizing tissue as the reference standard are necessary to help define the usage of PET/CT in patients with recurrent prostate cancer. **PET/CT has demonstrated promise in the detection of prostate cancer recurrence; however, its cost and variable clinical utility at extremely low**

PSA levels currently limit its widespread usage.

MRI can be used in the detection of local recurrence after biochemical failure. Sella et al. (2004) analyzed endorectal MRI in 48 patients with biochemical failure after radical prostatectomy and found a sensitivity and specificity of 95% and 100%, respectively. Lesions were isointense to muscle on T1-weighted images and slightly hyperintense to muscle on T2-weighted images. The mean PSA before imaging was 2.18 ng/mL but included 25 patients (64%) with PSA less than 1.5 ng/mL. The addition of dynamic contrast enhancement (DCE) has demonstrated an increase in accuracy over standard MRI with a sensitivity of 88%, specificity of 100%, positive predictive value of 100%, and negative predictive value of 88%. This was despite lower PSA values (mean 1.9 ng/mL) (Casciani et al., 2008). Furthermore, the combination of DCE and magnetic resonance spectroscopic imaging (MRSI) has demonstrated sensitivities as high as 86% in patients with PSAs in the 0.4 to 1.4 ng/mL range (Sciarra et al., 2008). **Compared with PET/CT, multiparametric magnetic resonance imaging (mpMRI) performs better in identification of local recurrence, especially at low levels of biochemical failure** (Panebianco et al., 2012).

Salvage Radiation Therapy

The state of a persistent or rising PSA after radical prostatectomy is challenging for patients and clinicians alike. Despite surgical management in patients with clinically localized prostate cancer, up to 40% of men will continue to harbor or develop a detectable PSA (Amling et al., 2000; Han et al., 2001; Hull et al., 2002; Roehl et al., 2004; Ward and Moul, 2005). Current limitations in imaging modalities to identify local versus metastatic disease, especially at low levels of PSA, create a treatment dilemma for clinicians. Despite being a noncurative treatment for a rising PSA after radical prostatectomy, approximately 60% of patients will undergo androgen deprivation therapy (ADT) as second-line treatment (Agarwal et al., 2008). **Salvage radiation therapy remains the clearest choice and best chance for long-term freedom from progression in men with PSA recurrence after radical prostatectomy.**

In 2004, a large multi-institutional group published the results of salvage radiation therapy in 501 patients who had a detectable or rising PSA after radical prostatectomy (Stephenson et al., 2004). Four-year freedom from progression was 45% despite including a significant portion of patients with high-risk features thought to predict for metastatic disease (high-grade disease and rapid

PSA doubling time) (Stephenson et al., 2004). On multivariable analysis, Gleason grade, pretreatment PSA, margin status, PSA doubling time, and seminal vesicle invasion were independent predictors of durable response (Stephenson et al., 2004). Other groups have demonstrated similar 5-year biochemical recurrence–free survival in 35% to 46% of patients treated with salvage radiation (Bastide et al., 2010 Buskirk et al., 2006; Geinitz et al., 2012;). Boorjian et al. (2009) demonstrated in their series of 856 men who received salvage radiation therapy that 534 (63.6%) achieved an undetectable PSA after therapy. On multivariable analysis, patients who received salvage radiation were at a 90% decreased risk for local recurrence, a 20% decreased risk for late administration of ADT, and a 75% decreased risk for systemic progression (Boorjian et al., 2009).

Although several groups have demonstrated the value of salvage radiation therapy in improving biochemical endpoints, Trock et al. (2008) reported that salvage radiotherapy, compared with observation, also improved disease-specific survival. They found a three-fold increase in disease-specific survival with salvage radiation compared with observation. This was identified in patients who received therapy within 2 years of biochemical recurrence and with a PSA doubling time of less than 6 months (Trock et al., 2008). It is clear that many patients will have a long-term, durable disease-free interval after salvage radiation. Further, Ying et al. (2017) also demonstrated that despite PSA failure after salvage radiation, the men in their cohort had a median overall survival of 13.6 years.

Failure after salvage radiation therapy can be a result of persistent local disease, recurrence of local disease, persistence of metastasis, or development of metastatic disease. It is important to identify factors that may predict for failure after salvage therapy for patient counseling and for surveillance. Using a large multi-institutional cohort of 1540 men, Stephenson et al. created a nomogram that predicts outcomes after salvage radiation therapy (Stephenson et al., 2007). PSA before salvage radiation, pathologic Gleason score, PSA doubling time, margin status, lymph node status, and ADT were included for the nomogram and had a concordance index of 0.69 (Stephenson et al., 2007). Furthermore, time to biochemical failure has been found to predict for development of distant metastatic disease, disease-specific mortality, and overall mortality (Johnson et al., 2013). Conversely, location and number of positive surgical margins are not predictive of biochemical recurrence after salvage radiation therapy (Bastide et al., 2010).

Previous studies have identified a PSA of 0.5 ng/mL or less as an appropriate cutoff for the initiation of salvage radiation (Heidenreich et al., 2014). Clearly, lower levels of PSA result in improved outcomes, as King confirms that for every increment of 0.1 ng/mL, there is a 2.6% loss of recurrence-free survival (King, 2012). This again is clearly shown in patient cohorts with long-term follow-up, where presalvage radiation therapy PSA values predict for eventual failure along with other parameters such as Gleason score, T-stage, and positive surgical margin (Rodin et al., 2017). The treatment dilemma for the clinician is finding a suitable cutoff for early therapy leading to good outcomes but sparing those who will not have clinical failure. This is especially true as radiation is not without some risk for side effects including cystitis and strictures, bowel complications such as proctitis, urgency and tenderness, along with erectile dysfunction and sexual bother. However, robust quality-of-life studies are lacking, and the risks for complications must be tempered compared with the potential for curative treatment (Raziee and Berlin, 2016). Recently, the incorporation of imaging data including mpMRI has garnered attention. The group from the Mayo Clinic has shown that the addition of mpMRI findings in a nomogram assisted in predicting failure of salvage radiation. They found that patients without prostate lesions on preoperative mpMRI were at a higher likelihood to have failure after salvage radiation for PSA failure as these patients may have occult metastatic disease (Sharma et al., 2018). Additionally, ^{68}Ga-PSMA-11 PET/CT scans have also shown significant promise in salvage radiation planning. In a study of 270 men with PSA recurrences less than 0.1 ng/mL, ^{68}Ga-PSMA-11 PET/CT identified 52/270 (19%) lesions outside of the planned radiation zone of which the most common sites were bone and perirectal (Calais et al., 2018).

Dose Response With Salvage Radiation Therapy

The primary treatment of prostate cancer with radiation therapy has taught us that higher dosages of treatment lead to improved prostate cancer outcomes with limited side effects (Zietman et al., 2005). Using the same logic, many groups have developed protocols of salvage therapy enhancing both the dosages administered and the planned targeting using intensity-modulated radiotherapy (IMRT) versus conformal therapy, which was administered in older cohorts (Buskirk et al., 2006; Geinitz et al., 2012). In 1999, the American Society for Therapeutic Radiology and Oncology (ASTRO) Consensus Panel released recommendations on salvage radiation stating that dosages of at least 64 Gy should be administered to the prostatic bed (Cox et al., 1999). Clearly, these guidelines are outdated, and more recent data demonstrate improved cancer control with higher dosages of therapy associated with minimal changes in side-effect profile.

De Meerleer et al. (2008) published their results with a planned target volume of 75 Gy in 37 fractions and demonstrated a biochemical freedom from disease of 67% at 5 years. There were no acute grade 3 gastrointestinal toxicities and only 3% genitourinary toxicities. Accordingly, there were minimal late gastrointestinal or genitourinary toxicities on further follow-up (De Meerleer et al., 2008). Gleason score at radical prostatectomy, perineural invasion, and capsular perforation of disease were all significant predictors of biochemical recurrence (De Meerleer et al., 2008). When stratifying patients into groups based on dosages of radiation; low (<64.8 Gy), moderate (64.8 to 66.6 Gy), and high (>66.6 Gy), the estimated cumulative rate of biochemical failure at 5 years was 57%, 46%, and 39%, respectively (Bernard et al., 2010). These results have been confirmed in a multi-institutional study of 10 institutions and 1108 patients in which a dosage of greater than 66.0 Gy correlated with reduced biochemical failure rates (Pisansky et al., 2016). Most recently, Ost et al. demonstrated that using a median dosage of 76 Gy, they achieved 5-year biochemical recurrence–free survival of 56% and clinical recurrence free survival of 86% (Ost et al., 2011). This was achieved while keeping toxicity rates low with total genitourinary grade 2 and 3 toxicities of 22% and gastrointestinal grade 2 and 3 toxicities of 8% (Ost et al., 2011). In a meta-analysis of 71 studies, increased salvage radiation doses conferred improved outcomes, where each increase in Gray resulted in a 2% improvement in recurrence free survival (King, 2016). **Modern series of radiation therapy using higher dosages clearly demonstrate improved cancer control results. Despite the biases involved with stage migration in more contemporary series, the improved toxicity profile with modern radiation delivery systems should make higher dosages of therapy the standard in salvage radiation therapy.**

Concurrent Androgen Deprivation Therapy With Salvage Radiation

Theoretically, the usage of systemic therapy with androgen deprivation may sterilize micrometastatic disease, shrink tumor burden making it more amenable to local salvage therapy, and potentially work in synergy with radiation therapy to treat remaining cancer cells. RTOG 96-01 is a trial comparing salvage radiation therapy (64.8 Gy) with and without 2 years of bicalutamide therapy for patients with a detectable PSA (0.2 to 4.0 ng/mL) at least 8 weeks after radical prostatectomy (pT3N0M0 or pT2 with positive margins). After 12 years of follow-up, results were recently published demonstrating an overall survival benefit of 76.3% versus 71.3% favoring the bicalutamide plus radiation arm. Further, death from prostate cancer at 12 years was 5.8% versus 13.4%, and incidence of metastasis was 14.5% versus 23% in favor of the bicalutamide plus radiation arm (Shipley et al., 2017). Additionally, the GETUG-16 trial of 743 men demonstrated an improvement in biochemical progression at 5 years with the addition of 6 months of goserelin to salvage radiation therapy with minimal adverse effects (Carrie et al., 2016). The RADICALS (Radiotherapy and Androgen Deprivation In Combination After Local Surgery) trial is a randomized phase III controlled trial evaluated the timing of radiotherapy (adjuvant vs. early salvage) and the duration of concurrent ADT. Patients will receive either none, 6 months, or 2 years of androgen deprivation with a gonadotropin-releasing hormone analogue or bicalutamide. The outcomes evaluated are disease-specific and overall survival (Parker et al., 2007). The results of the RADICALS trial may further support the addition of ADT to salvage radiation and perhaps give guidance regarding the ideal length of therapy.

Whole Pelvis Versus Prostatic Bed Radiation Therapy

Very few series evaluate the role of whole pelvis versus prostatic bed only salvage radiation therapy after biochemical recurrence. Spiotto et al. (2007) evaluated their experience in 160 men who underwent both adjuvant and salvage radiation therapy of which 114 were considered high-risk for lymph node involvement (Gleason score ≥8, preoperative PSA >20 ng/mL, seminal vesicle involvement, capsular extension, and lymph node positivity). Seventy-two patients received whole pelvis radiation versus 42 who underwent prostatic bed only radiation. The benefit of whole pelvis radiation was limited to those with high-risk features with 5-year biochemical recurrence–free survival of 47% versus 21% for prostatic bed alone (Spiotto et al., 2007). On multivariable analysis, whole pelvis radiation and preoperative PSA less than 1 ng/mL were predictors of biochemical recurrence–free survival (Spiotto et al., 2007). Furthermore, in patients with high-risk features, concurrent androgen deprivation with whole pelvis radiation conferred improved recurrence free survival (Spiotto et al., 2007).

Moghanaki et al. (2013) published their series of 247 patients undergoing salvage radiation therapy. This study compared two separate institutions with differing approaches to salvage radiation, with one group performing prostatic bed radiation (135 patients) and the other group performing pelvic nodal radiation in addition to prostatic bed radiation (112 patients) (Moghanaki et al., 2013). Pretreatment PSA and pathologic Gleason score were independent predictors of biochemical recurrence, but whole pelvic radiation was not an independent predictor associated with PSA recurrence free survival (Moghanaki et al., 2013). Even after separating patients into low- and high-risk features, there was no benefit to whole pelvis irradiation. However, when examining a subset of patients with preradiation PSA levels greater than or equal to 0.4 ng/mL, there was a 53% risk reduction in biochemical progression with whole pelvis radiation (Moghanaki et al., 2013). Conversely, in a retrospective multi-institutional study of 1861 patients with detectable PSA after radical prostatectomy for Gleason 7 or greater prostate cancer at 10 academic centers, whole-pelvis radiation was associated with improved 5-year freedom from biochemical failure of 62% versus 49% (Ramey et al., 2018). Clearly, results from retrospective analyses are limited by selection bias, and randomized trials are necessary.

RTOG 0534 is a randomized controlled trial currently accruing patients with high-risk prostate cancer features on radical prostatectomy and with postsurgery PSA greater than or equal to 0.1 ng/mL to less than 2.0 ng/mL. Patients will be stratified by seminal vesicle involvement, Gleason score, pretreatment PSA level, and stage. Patients will be randomized to prostatic bed radiation alone, prostatic bed radiation plus 6 months of androgen deprivation, and prostatic bed radiation therapy plus pelvic lymph node radiation therapy along with 6 months of ADT. Patients will either undergo three-dimensional CRT or IMRT at 64.8 to 70.2 Gy for the prostatic bed and 45 Gy for the pelvic lymph nodes. The primary objective is to evaluate freedom from biochemical progression, clinical failure, and overall survival. The results of this trial will help clarify this treatment dilemma (Figs. 160.2 and 160.3).

Salvage Versus Adjuvant Radiation Therapy for Prostate Cancer

Randomized phase III clinical trials are desperately needed to determine the role of adjuvant radiation versus early salvage radiation therapy. The RADICALS trial is a multi-institutional phase III clinical trial examining adjuvant radiation within 22 weeks of surgery versus early salvage therapy at PSA relapse, which is defined as either two consecutive rises in PSA level and a PSA greater than 0.1 ng/mL or three consecutive rises in PSA level (Parker et al., 2007). If biochemical recurrence is detected, patients will undergo either 66 Gy in 33 daily fractions over 6.5 weeks or 52.5 Gy on a 4-week treatment schedule. The RAVES (Radiotherapy—Adjuvant Versus Early Salvage) trial is a phase III trial randomizing patients with pathologic T3 disease and/or positive margins. The primary endpoint is biochemical cancer control, with secondary outcomes including quality of life, toxicity, anxiety/depression, biochemical failure free survival, overall survival, disease-specific survival, time to distant failure, time to local failure, time to initiation of androgen ablation, quality-adjusted life years, and cost-utility (Pearse et al., 2014). Finally, the GETUG-17 trial will evaluate a similar patient population but will randomize patients to immediate adjuvant radiation therapy versus observation patients and treat with salvage radiation when PSA levels read a level of 0.2 ng/mL. Both groups will undergo a short course of ADT. As these trials complete accrual and mature, we will gain a better understanding about the timing of radiation therapy along with the utility of concomitant ADT.

Androgen Deprivation Therapy for Biochemical Failure After Radical Prostatectomy

ADT in the postprostatectomy setting has been underevaluated, and the scope of its utility is lacking. Unfortunately, randomized controlled trials are limited, and the exact role in the comprehensive care of aggressive prostate cancer is not completely understood. Large retrospective series have demonstrated mixed results. Early ADT in men who have experienced biochemical recurrence has been found to decrease the rate of clinical metastasis in patients with high-risk features defined as Gleason sum greater than 7 or PSA doubling time less than 12 months (Moul et al., 2004). Delineation between early and late administration of androgen deprivation was significant at PSA cut points of 5 and 10 ng/mL (Moul et al., 2004). Similarly, the adjuvant ADT before signs of biochemical progression in select patients demonstrates improved 10-year progression-free and disease-specific survival (Siddiqui et al., 2011). This was true, even compared with a cohort of patients who received systemic therapy at PSA values of 0.4 ng/mL and above. Regardless of improvements in biochemical and disease-specific outcomes, there is no evidence of improved overall survival

(Siddiqui et al., 2011). Furthermore, the benefits in administration of ADT must be tempered by the potential for increased risk for cardiac disease and diabetes (Keating et al., 2006).

Not all patients who experience biochemical recurrence require ADT, and the identification of subgroups at highest risk for systemic failure will optimize selection and prevent morbidity. Patients with pathologic T3b tumors benefit from the adjuvant administration of ADT and experience improved 10-year biochemical progression free survival of 60% versus 16% (Siddiqui et al., 2008). These patients also demonstrated improved local recurrence-free, systemic progression-free and disease-specific survival. But again, there was no statistically significant improvement in overall survival (Siddiqui et al., 2008). Patients with high-risk features, such as Gleason score of 8 or higher; PSA 15 ng/mL or higher; pathologic stage T3b, T4, or N1; or Gleason score 7 with concomitant PSA greater than 10 ng/mL or a positive margin, were found to have a biochemical failure–free survival of 92.5% at 5 years, with an overall survival of 95.9% in patients treated with adjuvant ADT as part of a randomized clinical trial (Dorff et al., 2011). Patients who have positive lymph nodes at radical prostatectomy are at highest risk for micrometastatic disease and eventual systemic failure. In a randomized clinical trial of immediate versus deferred ADT, patients who received immediate therapy demonstrated improved overall survival, disease-specific survival, and progression-free survival at a follow-up of 11.9 years (Messing et al., 2006).

In patients with persistent or rising PSA after definitive therapy for prostate cancer (radiation or prostatectomy), a retrospective analysis of 2096 men using the CaPSURE database found similar survival whether ADT was initiated within 3 months of PSA recurrence versus within 3 months of clinical progression (Garcia-Albeniz et al., 2015). Similarly, in a report of 5804 men within three large managed care health care organizations, salvage ADT was not associated with decreasing all-cause or disease-specific mortality. However, there was a benefit in all-cause and disease-specific mortality in patients with PSA doubling times less than 9 months (Fu et al., 2017). **Clearly, patients at the highest risk for local and systemic recurrence are those who likely benefit the most from adjuvant hormone therapy.**

Radiation Therapy

PSA Recurrence After Definitive Radiotherapy

Similar to PSA recurrence after radical prostatectomy, biochemical recurrence after definitive radiotherapy precedes clinical failure. This gives warning of potential disease progression to initiate secondary/salvage therapies.

In 2005, a multidisciplinary panel of experts met in Phoenix, Arizona, to discuss a new definition of biochemical failure after definitive radiation therapy for prostate cancer (Roach et al., 2006). This group defined PSA recurrence as a rise of 2 ng/mL or more above the nadir PSA and the date of failure was at call (Roach et al., 2006). Importantly, the stated biochemical outcomes should be 2 years short of the median follow-up for the group to avoid any overestimations of biochemical recurrence–free survival. Furthermore, the definition was created for usage in patients who also received concurrent ADT (Roach et al., 2006).

It is now clear that the “Phoenix” definition of biochemical recurrence is more robust in predicting clinical outcomes. In a contemporary series of definitive radiotherapy for prostate cancer, 1831 men with clinical stage T1 to T4 prostate cancer without nodal or metastatic disease was compared using the ASTRO and Phoenix definitions of biochemical recurrence to predict for metastatic disease, disease-specific mortality, and overall mortality (Abramowitz et al., 2008). Accounting for covariates such as T-stage, initial hormonal treatment, Gleason score, radiation dosage, PSA, and age, the **Phoenix definition was found to be a significant predictor of metastatic disease, disease-specific mortality, and overall mortality on univariable and multivariable analysis.** The ASTRO definition was significant for metastatic disease and disease-specific mortality to a lesser degree and not significant at all for overall survival (Abramowitz et al., 2008). In fact, on multivariable analysis, PSA nadir +2 ng/mL was the most significant predictor of all three outcomes compared with all other covariates, confirming the validity of this definition of PSA recurrence (Abramowitz et al., 2008).

Postradiation PSA Bounce

Postradiation PSA “bounce” is a varied definition of an elevated PSA of 0.1

ng/mL to 0.5 ng/mL over the prebounce PSA with a subsequent decrease in PSA (Cavanagh et al., 2000; Critz et al., 2000; Hanlon et al., 2001; Rosser et al., 2002). It is thought that this phenomenon occurs secondary to post-treatment prostatitis (Critz et al., 2000) or even from the delivery of a sublethal dosage of radiation with associated delayed cellular death. Rosser et al. (2002) defined PSA bounce among their cohort as a rise of PSA of at least 0.5 ng/mL followed by a decrease to baseline value and found in their group of men that the bounce occurred at a mean time of 9 months from therapy and was associated with an improvement in biochemical recurrence–free survival compared with those who did not have a bounce. These results have recently been confirmed in men undergoing dose escalation. In 776 patients with a median radiation dose of 81 Gy, PSA bounce (≥2 ng/mL above nadir with return to nadir or below) correlated with decreased risk for eventual PSA recurrence, distant metastasis, and all-cause mortality at a median follow-up of 9.2 years (Romesser et al., 2018). Series of brachytherapy in addition to external-beam radiation demonstrate similar rates of PSA bounce of approximately 35% (Cavanagh et al., 2000; Critz et al., 2000). Additionally, the probability of PSA bounce may depend on fraction size in high-dose-rate brachytherapy (Hauck et al., 2017). **It is quite clear that patients who undergo a transient rise in their PSA should be closely monitored as not all men are destined for biochemical failure, let alone clinical failure.**

Natural History of PSA Recurrence After Definitive Radiation

PSA-only recurrence after definitive radiation therapy for prostate cancer leads to clinically relevant outcomes such as local and distant failure along with disease-specific death. Lee et al. (1997) demonstrated in their cohort of 151 men that men with higher pretreatment PSA levels, higher Gleason scores, and higher stage were more likely to develop an increasing PSA profile (PSA ≥1.5 ng/mL on two occasions). Furthermore, 5 years after PSA elevation, the estimated rate of local recurrence was 26% and distant metastasis was 47% (Lee et al., 1997). Overall and disease-specific survival at 5 years was 65% and 76%, respectively (Lee et al., 1997). Although rapid PSA doubling time and short interval from treatment to PSA elevation were predictors of subsequent metastatic disease, Gleason grade was the only predictor for overall and disease-specific survival (Lee et al., 1997).

In a larger series of 2694 men treated with radiation therapy (75.6 to 86.4 Gy), 609 men experienced biochemical recurrence defined as PSA nadir greater than 2 ng/mL. Of these men, the median time to metastasis and disease-specific death was 5.4 years and 10.5 years, respectively. Predictors of clinical significant outcomes were shorter post-treatment PSA doubling time, pretreatment clinical stage, Gleason score, and short interval from radiation to biochemical recurrence (Zumsteg et al., 2015). Men with PSA elevation after definitive radiotherapy are candidates for salvage therapy. Defining those at greatest risk for local versus distant failure is key to deciding on second-line therapy. Further, patient comorbidity and age must be considered before initiation of treatment.

Biopsy After Radiotherapy

The goals of biopsy after definitive radiation is to identify the presence or absence of locally residual or recurrent disease and to identify grade of remaining disease. Crook et al. (2000) recommended biopsies to be performed at least 2 to 3 years after the completion of radiation therapy to decrease the rates of false-positive and false-negative biopsies. Biopsy based on guided ultrasonography or MRI should target abnormal lesions, the seminal vesicles, and a systematic sampling of the entire prostate gland. The information from prostate biopsy will guide further treatment strategies and should be reserved for patients in which salvage local therapy is considered. One should keep in mind that tumor architecture is altered after radiation therapy and may represent dedifferentiation of cancer cells. Further, Gleason grading after radiation therapy may or may not be accurate, and its utility is controversial (Cheng et al., 1998, 1999; Letran et al., 1998).

Imaging After Biochemical Recurrence Following Radiotherapy

Imaging of the prostate after definitive radiotherapy remains challenging with traditional modalities because of fibrosis and shrinkage of the prostate (Martino et al., 2011). Transrectal ultrasonography has limited ability to identify suspicious lesions of the prostate and has a sensitivity and specificity profile no better than rectal examination (Crook et al., 1993). Furthermore, although CT is useful for the detection of bone and lymph node metastasis in patients with significantly elevated PSA levels (>20 ng/mL), the ability to identify recurrent cancer after radiotherapy is limited. Recently, MRI has emerged as the most promising technique for identifying recurrent tumors of the prostate in biochemical recurrence.

T2-weighted MRI of the prostate is capable of excellent soft tissue differentiation; however, its usage in postirradiated tissue is limited by diffusely decreased signal intensity in the prostate (Coakley et al., 2001). Sensitivity of T2-weighted MRI is as low as 27% with limited positive predictive value of 32% (Kim et al., 2010). Therefore, dynamic imaging studies have been pursued to better identify potential recurrent lesions amenable for salvage therapy. DCE gives the ability to identify vascularization of the prostate and tumor along with angiogenesis and capillary permeability characteristics (Franiel et al., 2011). When comparing DCE-MRI with T2-weighted MRI, DCE-MRI had better sensitivity (72% vs. 38%), positive predictive value (46% vs. 24%), and negative predictive value (95% vs. 88%). Specificity was similarly high for both groups (Haider et al., 2008). Yakar et al. (2010) determined that the combination of DCE imaging along with MRI-guided biopsy of suspicious lesions led to a positive predictive value of 75% and 68% for per patient and per tumor suspicious region, respectively.

MRSI distinguishes residual prostate cancer by identifying a relative increase of choline plus creatinine-to-citrate ratio or by identifying an increase in the choline peak with no citrate identified. Using these criteria, MRSI has demonstrated sensitivity of 77% compared with sextant biopsy and rectal examination, which revealed sensitivities of 48% and 16%, respectively, in the same patient cohort (Pucar et al., 2005). However, it is important to note that benign glands can exhibit high choline levels after radiation and may cause false-positive findings (Pucar et al., 2005). Furthermore, the addition of MRSI to T2-weighted imaging significantly improved the detection of locally recurrent prostate cancer after radiation therapy (Westphalen et al., 2010).

Diffusion-weighted imaging magnetic resonance imaging (DWI-MRI) has also demonstrated feasibility in the clinical setting. Kim et al. (2010) found the utility alone and in combination of DCE imaging revealing an accuracy of biopsy as high as 83%. This was in comparison to T2-weighted MRI, which demonstrated an accuracy rate of 67% (Kim et al., 2010). Further illustrating the benefit of DWI-MRI, Hara et al. (2012) found a sensitivity and specificity of 100% and 100%, respectively, on a per-patient basis when comparing MRI findings to a 22-core three-dimensional prostate mapping biopsy as the standard reference. On a region-by-region basis, the sensitivity and specificity was 69%

and 91%, respectively. Abd-Alazeez et al. (2015) recently demonstrate that their receiver-operator characteristic area under the curve was as high as 0.84 when using mpMRI in radiorecurrent prostate cancer when using transperineal systematic template prostate mapping as the standard. Additionally, the Mayo Clinic report their experience in patients undergoing mpMRI using a 3 Tesla magnet and endorectal coil before salvage radical prostatectomy and found reasonable accuracy for detecting extraprostatic extension, seminal vesicle invasion, and lymph node metastasis (Zattoni et al., 2017). These data demonstrate the utility of MRI in patients with biochemical recurrence after radiation therapy. The optimal timing of MRI and level of PSA at imaging are yet to be determined and will need further investigation.

^{68}Ga-PSMA PET scanning has demonstrated utility in patients who fail after radiation therapy. In a large series of 419 men, 70 were found to have biochemical failure defined by the Phoenix definition of which 48 men underwent ^{68}Ga-PSMA PET scans. With a median PSA of 5 ng/mL, all patients were found to have “unequivocally positive” positive scans. There were 25 distant failures, 15 local and distant failures, and 8 local only failures (Hruby et al., 2017). Parker et al. (2017) evaluated ^{11}C-choline PET/CT in 184 patients who met the Phoenix definition of PSA recurrence after radiotherapy. They identified 161/184 patients with positive ^{11}C-choline PET/CT scans, with 54.3% within the pelvic soft tissue and 33% with extrapelvic disease. On multivariable analysis, they determined that the difference between PSA nadir and PSA at PET scan, time from radiation therapy, and National Comprehensive Cancer Network (NCCN) risk groups were predictive of distant disease. Additionally, the authors created a nomogram with a predictive index of 0.79. Clearly, sensitive scans that can detect local versus distant failures are critical in deciding on the utility of local salvage therapies.

Salvage Radical Prostatectomy

Salvage radical prostatectomy is considered the most definitive way to eradicate localized radiorecurrent prostate cancer. Despite the infrequent usage of salvage surgery in the setting of radiorecurrence, multiple studies have demonstrated the 10-year disease-specific survival to be as high as 70% to 83% (Bianco et al., 2005; Chade et al., 2011; Lerner et al., 1995; Ward and Moul, 2005). However, survival outcomes directly correlate with pathologic stage whereby organ-confined disease and isolated extracapsular extension confer a 5-year progression-free probability of 77% and 71%, respectively. Conversely, those with seminal vesicle invasion and lymph node involvement have poorer 5-year outcomes of 28% and 22%, respectively (Bianco et al., 2005; Stephenson and Eastham, 2005). Given the high propensity for prostate cancer to recur despite radiation therapy, it is of utmost importance to treat with definitive salvage therapy before local invasion and metastasis.

Despite successful cancer outcomes in traditional and contemporary series of salvage radical prostatectomy, the hesitance to perform such operations is a result of the inherent risks of significant morbidity. Historically, up to 50% of patients who undergo salvage surgery will suffer a major complication (Moul and Paulson, 1991). As a result of significant fibrosis from radiation, rectal injury rates of 6% to 15% and bladder neck contracture rates of 20% to 28% have been reported. Further, rates of urinary incontinence ranged from 40% to 60% (Lerner et al., 1995; Rogers et al., 1995). It is worth mentioning that in these surgical series, some patients had received preradiation pelvic lymph node dissection; retropubic brachytherapy; and nonconformal radiation delivery, which added to the morbidity. As a result of the high complication rates, clinicians have been hesitant to perform salvage radical prostatectomy. This is reflected in the CaPSURE database demonstrating that only 2% of patients underwent surgery as secondary treatment after radiation failure, and 92% underwent noncurative ADT (Grossfeld et al., 2002). **Patients selected for salvage radical prostatectomy should have biopsy-proven radiorecurrent prostate cancer, at least 10 years of life expectancy, lack of identifiable metastasis on imaging, and a PSA of less than 10 ng/mL (Table 160.2).**

Within the past 10 years, there has been a preponderance in robotic-assisted laparoscopic prostatectomy, and naturally this approach has begun to gain favor among urologists who are willing to tackle salvage prostatectomy. Perceived advantages to the robotic approach include decreased blood loss, better visualization, and shorter hospitalization. In a meta-analysis of 197 patients undergoing robotic salvage prostatectomy, Zargar et al. (2017) demonstrated that approximately two-thirds of all patients were free from recurrence. Additionally, 60% were continent, 26% were potent, and 16% suffered complications requiring intervention. As both data and surgeon experience mature, both oncologic and morbidity outcomes will likely demonstrate improvement. Similar to open surgery, patient selection and close adherence to surgical principles are of utmost importance.

Salvage Cryotherapy

In the United States, approximately one-third of newly diagnosed men with prostate cancer are treated with external-beam radiation and/or brachytherapy as the primary modality of therapy (Mettlin et al., 1998, 1999). Depending on the series and definition, approximately 30% to 40% of patients treated with primary radiation will have failure (Crook et al., 2000; D'Amico et al., 2008; Shipley et al., 1999; Touma et al., 2005). In the carefully selected patient, cryotherapy may be an effective and safe option for treatment of radiorecurrent disease.

Patients best suited for cryotherapy are those with localized treatment failure after radiation therapy with biopsy-proven disease as approximately one-third of patients with biochemical failure will have a positive biopsy (Crook et al., 1995). Regardless of definition, biochemical failure determination and histologic failure is ideally identified at least 2 years after primary treatment to account for PSA bounce and ongoing histologic changes postradiation (Chin et al., 2007; Crook et al., 2000). In addition to standard, multicore prostate biopsy, it may be prudent to include the seminal vesicles as up to 29% may have involvement and predict for poor outcomes (Gheiler et al., 1998). Candidates for salvage cryotherapy should have a reasonable life expectancy and must undergo a full metastatic workup with cross-sectional imaging (CT abdomen/pelvis or MRI) along with a radionuclide bone scan (Babaian et al., 2008). Pelvic lymph node biopsy may also be considered in high-risk patients (Babaian et al., 2008). Patients with a presalvage PSA of less than 10 ng/mL, ideally less than 4 ng/mL (Ng et al., 2007), and a PSA doubling time greater than or equal to 16 months have been shown to be predictive for successful treatment (Spiess et al., 2006).

To date, there is no universal definition of “success” using salvage cryotherapy. Using a definition of 2 ng/mL above the postcryotherapy nadir, Pisters et al. (1999) demonstrated a 74% 2-year disease-free survival for patients with a postradiation PSA less than 10 ng/mL and 58% for patients with a preradiation Gleason score of 8 or less. In a contemporary analysis of the COLD (cryo on-line data) Registry including 156 patients, 3-year biochemical disease-free survival using the Phoenix definition of nadir plus 2 ng/mL was determined to be 66.7% (Spiess et al., 2013). Williams et al. (2011) report their outcomes in 176 patients with a mean follow-up of 7.46 years. Primary outcome of overall survival was 95%, 91%, and 87% at 5, 8, and 10 years, respectively.

Clearly, the success of any salvage therapy is tempered by the significant risks for side effects. Third-generation cryotherapy involves the adoption of a liquid Argon gas system, smaller-diameter probes, a pinpoint thermocoupler, and continued usage of transrectal ultrasound guidance and urethral warmers. Historically, salvage cryotherapy was wrought with a high complication rate. In terms of urinary morbidity, one of the largest quality-of-life series of 112 men demonstrated that 72% of men had urinary incontinence, with 66% of men describing their symptoms as moderate to severe in nature. Only 33% felt satisfied by the therapy they had received (Perrotte et al., 1999). However, more recent data demonstrate improved urinary incontinence rates from 4.3% to 6.5% (Bahn et al., 2003; Donnelly et al., 2005; Pisters et al., 2008). This drastic improvement in results is likely caused by the universal usage of urethral warming, which helps protect the urinary sphincter mechanism. Erectile dysfunction has been difficult to gauge in salvage cryotherapy series secondary to inconsistent reporting and lack of validation. In the series from Perrotte et al. (1999), 15% of patients who were potent pretreatment maintained erectile function sufficient for sexual intercourse. Ismail et al. (2007) reported a rate of erectile dysfunction of 86%. Clearly, erectile dysfunction is a significant risk from the primary treatment, and further cryotherapy is likely to worsen symptoms. Current exploration into nerve-sparing and subtotal cryotherapy is underway. The most dreaded complication risk for salvage cryotherapy is urethrorectal fistula, which has decreased significantly in recent series. Some reports demonstrate lower rates of 1% to 3.4% (Bahn et al., 2003; Ismail et al., 2007; Ng et al., 2007; Pisters et al., 2008). Other reported complications include urinary obstruction, urethral sloughing, urethral stricture, rectal pain, scrotal edema, and hematuria (Chin et al., 2007; Finley and Belldegrun 2011). Recently, Li et al. (2015) reported outcomes from the COLD registry using focal cryotherapy. In 91 patients, biochemical recurrence–free survival was 95.3%, 72.4%, and 46.5% at 1, 3, and 5 years, respectively. There was a 3.3% rate of rectourethral fistula, 6.6% rate of urinary retention, 5.5% rate of incontinence, and 10 of 20 patients who were potent before salvage cryotherapy were potent afterward. It is clear that in the carefully selected patient, salvage cryotherapy is a reasonable approach with adequate disease-specific outcomes and limited morbidity (Table 160.3).

Salvage Brachytherapy

The evidence for salvage brachytherapy after radiation failure is lacking compared with salvage prostatectomy and salvage cryotherapy. However, several groups have published contemporary series including modern techniques that not only demonstrate improved cancer control outcomes but also have comparable morbidity outcomes to cryotherapy and surgery. Randomized controlled trials of salvage therapies are desperately needed.

Recently, high-dose rate brachytherapy (HDRB) has gained attention as it has the ability to implant the seminal vesicles and treat extracapsular extension while limiting the dosage to surrounding organs through a conformal delivery (Chen et al., 2013; Hsu et al., 2005; Syed et al., 2001). In the largest series of HDRB, 52 patients underwent therapy, with a median follow-up of 59.6 months. All patients had biopsy-confirmed recurrent disease, negative workup for systemic disease, and no previous prostatectomy. Patients received 36 Gy in 6 fractions in two separate implants 1 week apart (Chen et al., 2013). The 5-year overall survival was 92%, and biochemical recurrence–free survival was 51%. As expected, patients with lower post-therapy nadir were more likely to have biochemical recurrence–free survival (Chen et al., 2013). Only one patient had distant failure and had a nadir PSA of 7.2 ng/mL. The toxicity profile was excellent in this cohort, with only one patient having a grade 3 acute and late genitourinary toxicity and no patients having any grade 3 or 4 acute or late gastrointestinal toxicity (Chen et al., 2013). Although no factors were statistically significant as predictors for biochemical outcome, the factors that were borderline in significance were disease-free interval after initial definitive radiation, percent of positive cores at diagnosis, time from recurrence to salvage HDRB, and presalvage therapy PSA (Chen et al., 2013). More recently in a cohort of 22 patients with at least 60 months of follow-up, 5-year biochemical free survival was 45% with minimal urinary or gastrointestinal-related side effects (no grade 3 or above) (Jiang et al., 2017). Salvage HDRB is a promising modality for patients with radiorecurrent prostate cancer. Similarly to low-dose-rate brachytherapy, patients likely to be most suitable are those with prolonged disease-free interval from primary treatment to recurrence, longer PSA doubling times, Gleason score less than or equal to 6, PSA less than 10 ng/mL, and no evidence of extracapsular extension or seminal vesicle invasion (Beyer, 2003). Recently, an analysis of low-dose versus high-dose brachytherapy was performed in 98 patients. After a median follow-up of 31 months, there were no difference in PSA recurrence-free survival and no difference in toxicity. Additionally, only PSA doubling time before salvage therapy was predictive of eventual PSA failure (Kollmeier et al., 2017).

Salvage High-Intensity Focused Ultrasonography

Salvage high-intensity focused ultrasonography (HIFU) has been evaluated in the treatment of radiorecurrent prostate cancer with acceptable cancer control outcomes. In an open-label clinical trial between 2009 and 2012, 100 men were enrolled at 16 sites to receive salvage HIFU at least 2 years after external-beam radiation. Primary end points were a PSA nadir of 0.5 ng/mL or less along with a negative prostate biopsy at 12 months. Of the 78 patients who completed the 12-month biopsy, 63 (81%) were negative for cancer. Additionally 50/78 patients achieved a PSA nadir below 0.5 ng/mL in conjunction with the negative biopsy. There were 80 patients with grade 2 toxicity and 20 patients with grade 3 toxicity. These included 5 men with rectal fistulas, 3 patients with osteitis pubis, and 3 who had recalcitrant hematuria requiring intervention (Jones et al., 2018). Although short- to intermediate-term follow-up has been demonstrated with HIFU, further studies are necessary to establish its place as a viable alternative in the radiorecurrent setting.

Androgen Deprivation Therapy After Biochemical Recurrence Following Radiation Therapy to the Prostate

PSA elevation after definitive radiotherapy may be a result of local versus distant metastatic disease. Patients with biopsy-proven local disease, no evidence of distant metastatic disease, and substantial life expectancy should be counseled about salvage local therapy such as prostatectomy, radiation approaches, and cryotherapy. Some patients may refuse local therapy, may have too many comorbidities to undergo potentially morbid procedures, or have decreased life expectancy. Even in younger patients who are candidates for local therapy, survey results demonstrate that up to 54% of clinicians would recommend observation or ADT. This is more pronounced in a scenario of older men, where 78% would recommend observation or ADT (Sylvester et al., 2001). The reality is that 93.5% of men undergo ADT as second-line therapy after radiation failure, and therefore this approach should be clearly defined (Agarwal et al., 2008).

Not all patients with biochemical recurrence after radiation approaches are destined for clinical failure. Defining the patient population who is at highest risk is important to treat the patients with early ADT who are likely to benefit while sparing the significant side effects to those who are at low risk to fail. PSA doubling time has consistently demonstrated the ability to predict the patients who are at highest risk for failure after radiotherapy and has been linked to freedom from biochemical recurrence, local relapse, distant metastasis, and increased overall survival (Hanks et al., 1996; Lee et al., 2005; Pollack et al., 1994; Zelefsky et al., 2005). Although multiple cut points under 12 months have been described to be significant for increased risk for clinical failure, it is likely that this end point is linear (D'Amico and Hanks, 1993), and clinical judgment must be used taking into consideration the patient's comorbidities and likelihood of disease-related death for the initiation of ADT. Furthermore, side effects of ADT therapy including sexual side effects, hot flashes, decreased bone mineral density, decreased muscle mass, cognitive dysfunction, metabolic syndrome, potential cardiovascular morbidity, fatigue, anemia, and depression must be taken into consideration (Cherrier et al., 2003; D'Amico et al., 2007; Green et al., 2002; Higano et al., 2004; Harle et al., 2006; Keating et al., 2006; Spry et al., 2009).

Considering the potential morbidity of ADT and the substantial cost, it is reasonable to start treatment in those patients at highest risk for distant failure. This is confirmed as patients with PSA doubling times less than 12 months have been demonstrated to benefit from ADT with freedom from distant metastatic disease of 57% versus 78%. Further, patients who received ADT had median time from distant failure of 6 months compared with 25 months (Pinover et al., 2003). This benefit of therapy with ADT was not seen in the patient cohort with PSA doubling time greater than 12 months, confirming the notion that patients at decreased risk for systemic disease are unlikely to benefit from the early initiation of systemic therapy. Faria et al. (2006) reviewed their series of 113 men with long PSA doubling time of 26.4 months who experienced biochemical failure but did not undergo ADT. At a median follow-up of 43 months, no patients had died of prostate cancer, but 12 patients had died from other causes. These data illustrate the importance of risk stratification in patients after biochemical recurrence after radiation therapy. Recently, the results of a randomized trial of immediate versus delayed ADT in men with biochemical failure after attempt at definitive therapy (surgery and/or radiation) or in patients not suitable for definitive therapy demonstrated an improvement in overall survival in the immediate therapy arm. However, this benefit does come with detrimental effects on quality of life (Duchesne et al., 2016, 2017). Lastly, the ideal management of PSA recurrence in patients at high risk for failure may be the initiation of intermittent ADT. In a recent clinical trial, intermittent ADT was found to be noninferior compared with continuous therapy in patients with PSA levels greater than 3 ng/mL without evidence of metastatic disease. This came with the benefit of potential improvement in physical function, fatigue, urinary problems, hot flashes, libido, and erectile function (Crook et al., 2012). Clearly, further studies are necessary to identify the ideal timing of ADT initiation, the benefits of intermittent ADT, and the ideal patient group who will benefit the most from therapy.

Summary

Patients who experience biochemical recurrence after primary therapy of prostate care are at higher risk for clinical progression and anxiety from disease progression. However, not all men with PSA progression will experience clinically significant outcomes such as metastasis, need for secondary treatment, and death from prostate cancer. Therefore, risk stratification is of the utmost importance. Furthermore, advances in diagnostic imaging and therapeutics will improve the identification of those with local recurrence and enhance cancer eradication with limited morbidity.

Key Points

- The AUA and the EAU have defined biochemical recurrence after radical prostatectomy as a value of greater than or equal to 0.2 ng/mL with a second confirmatory value.
- Salvage radiation therapy should be discussed with patients with nonmetastatic prostate cancer and a rising PSA after radical prostatectomy.
- ADT should be considered in patients receiving salvage radiation therapy, especially in those with high-risk features.
- mpMRI can be a useful tool for detection of local recurrence after radical prostatectomy.
- Patients who undergo a transient rise in their PSA should be closely monitored, because not all men are destined for biochemical failure, let alone clinical failure.
- The ideal candidate for salvage radical prostatectomy has at least 10 years of life expectancy, lack of metastasis on imaging, and a PSA less than 10 ng/mL.

Hormonal Therapy for Prostate Cancer

Scott Eggener MD

Historical Overview

The seeds of androgen ablation therapy date back as far as 1786, when Hunter described seasonal variation in prostate size among animals (Palmer, 1893). As early as 1893, White proposed castration to treat urinary obstruction disorders based upon his research on aging dogs (White, 1893). The impact of castration on metastatic prostate cancer was championed by Charles Huggins in 1941, when he and Clarence Hodges reported **"significant improvement often occurs in the clinical condition of patients with far advanced cancer of the prostate after they have been subjected to castration. Conversely, the symptoms are aggravated when androgens are injected"** (Huggins, 1941). This paradigm shift in cancer therapy initiated the era of hormone therapy for prostate cancer for which Huggins received the Nobel Prize in 1966. The Nobel committee noted Huggins' discoveries have "already given many years of an active and useful life to patients with advanced cancer over the entire civilized world—patients who would have been lost to other forms of therapy."

Critical to understanding the control of prostatic volume by hormones was the discovery of testosterone. It had long been known that extracts of male testicles exhibited invigorating effects when injected into humans. In 1926 Fred Koch and colleagues at the University of Chicago isolated 20 mg of testosterone from 40 lb of bull testes obtained from the local stockyards (Gallagher, 1929). To illustrate its effect, they injected a neutered rooster (capon) with the substance, and within a few weeks the animal exhibited the appearance and behavior of a hormonally intact rooster. In 1935 Laqueur determined the molecular structure and Ruzicka and Butendant reported the ability to synthesize testosterone from cholesterol (Butenandt, 1935; David et al., 1935; Ruzicka, 1935).

Huggins' seminal work on prostate cancer was greatly aided by the work of Kutscher and Wohlbergs, and Gutman and Gutman (1938), who reported the discovery of serum prostatic acid phosphatase (PAP) in humans and dogs, which served as an early biomarker to track prostatic volume, much like prostate-specific antigen (PSA) is used currently. Large amounts of acid phosphatase were found in the prostate glands of men, monkeys, and dogs, in primary and metastatic prostate cancer (Gutman et al., 1936), and levels appeared to be associated with testosterone levels. Serum levels of acid phosphatase were increased in men with disseminated prostate cancer (Gutman and Gutman, 1938). **A key step was the localization of the phosphatase to prostatic**

epithelial cells, including primary and metastatic prostatic cancer cells. Subsequently, Huggins demonstrated administration of estrogen in dogs mimicked the effects of castration and resulted in prostatic atrophy, reporting that castration or estrogen administration resulted in rapid atrophy of enlarged prostates of older dogs (Huggins and Clark, 1940).

Extending his findings to humans, Huggins also reported in 1940 that castration had beneficial effects for benign prostatic hyperplasia. In 1941 Huggins published three seminal papers under the heading "Studies on Prostate Cancer I-III" (Huggins and Hodges, 1941; Huggins et al., 1941a,b). **In an important prelude to current cell-of-origin studies, Huggins examined acid phosphatase levels in prostate tissues and demonstrated increased phosphatase expression in prostate tumors, normal adult, and hypertrophic prostate, but little to undetectable enzyme in newborn infant prostate tissues** (Huggins, 1941)**. Consequently, Huggins made an important observation: "Prostatic carcinomas examined consisted of a malignant type of adult epithelium rather than of neoplastic cells of a more primitive type"** (1941). In "Studies on Prostate Cancer II" they conducted orchiectomies on 21 patients, 15 of which had detectable metastatic disease. Huggins et al. (1941b) reported "noticeable improvement" in all but three patients and demonstrated a "prompt and sharp reduction" in serum acid phosphatase levels that was maintained for many months after orchiectomy. **Huggins also noted consistent weight gain, upward red blood cell count, significant improvement of pain symptoms, edema of lower extremities, loss of sexual capacity, and hot flashes** (Huggins, 1941)**. Most importantly, this included prolonged patient survival and improved quality of life.** Case 1, marked by Huggins as "A.J.", was 50 kg with urine retention and metastatic prostate cancer, including extensive osteolytic metastases to both sides of the pelvis, with a pathological fracture of the right pubis. He was castrated on Oct 16, 1939, and on March 20, 1941, was 64 kg with no apparent cancer-related symptoms (Huggins, 1941).

No less significant than the use of surgical orchiectomy for advanced metastatic disease was the use of oral estrogens to accomplish the same effect. In the 1960s this approach was vetted by the Veterans Administration Cooperative Urologic Research Group (VACURG), when they compared the estrogen diethylstilbestrol (DES) with orchiectomy for advanced prostate cancer and found them equally effective. However, it was also found that lowering testosterone using oral estrogens caused significant cardiovascular and thromboembolic toxicities (Byar, 1973; Byar and Corle, 1988).

Unfortunately, for the men benefitting from Huggins' significant discoveries, the eventual development of castration-resistant disease progression meant hormone therapy was rarely curative and eventually led to a more aggressive and lethal form of the disease. Huggins suspected a key role for adrenal androgen synthesis in producing enough androgens to support prostate cancer growth and attempted bilateral adrenalectomies to men with castration-resistant prostate cancer (CRPC) (Huggins and Scott, 1945). Such an approach led to modest, short-term responses but carried severe shortcomings revolving around the surgical approach and side effects of removing both adrenal glands.

Given the substantial need for new avenues of decreasing testosterone production for prostate cancer treatment, other labs directed their attention upstream of testosterone-secreting cells to endocrine signaling by the hypothalamic-pituitary-gonadal axis. First, the mechanistic underpinnings of estrogens decreasing testosterone production was demonstrated by Swerdloff and Walsh, whereby estradiol potently inhibited luteinizing hormone (LH) secretion (Walsh et al., 1973). Second, the isolation of luteinizing hormone–releasing hormone (LHRH) by Schally et al. (1971) led to the development of synthetic LHRH analogues (agonists and antagonists). Such LHRH agonists lead to an initial surge of testosterone release (i.e., flare) but ultimate loss of pituitary stimulation results in decreased LH levels and decreased production of testosterone by Leydig cells. LHRH agonists were then re-engineered as long-acting depot preparations, lasting several months, and established LHRH agonists as the dominant treatment in hormone therapy for prostate cancer.

The discovery of the protein target for hormone therapy, the androgen receptor (AR), ushered in a new era of chemical anti-androgenic compounds directly blocking the key oncogenic driver of prostate cancer. **Such therapies attempt to interrupt ligand-receptor binding to reduce AR activity and signaling in prostate cancer cells.** However, many antiandrogenic compounds block feedback to the hypothalamic-pituitary axis, leading to increased LH and testosterone production when used as single agents without concurrent chemical or surgical castration.

Molecular Biology of the Androgen Axis

The AR is a member of the nuclear receptor superfamily, which includes receptors for the sex steroids (androgen, estrogen, progestin), adrenal steroids (mineralocorticoids, glucocorticoids), thyroid hormones, vitamin D, and retinoids. **These receptors act as ligand-inducible transcription factors, containing three key functional domains: ligand-binding (LBD), DNA-binding, and transactivation.** Membrane-permeable steroid ligands diffuse into the cell, where they engage the LBD and activate the DNA-binding domains; the transactivation domain binds and recruits other gene transcriptional partners to thus regulate gene expression, either by repression or activation (Fig. 161.1). **The AR gene is located on the X chromosome, meaning only one copy is inherited in XY males.** Sequencing, ligand-binding, and transcriptional activation of mutant AR forms from cancer and androgen insensitivity syndromes have enabled detailed functional mapping of the AR to identify key amino acids necessary for proper function (Gottlieb et al., 2012). Proper regulation of the AR is essential for prostate development, adult glandular homeostasis, and cancer progression. Furthermore, all forms of androgen deprivation therapy (ADT) orbit around blocking AR activity, either by reducing levels of AR ligand or inhibiting AR activity directly (Table 161.1).

TABLE 161.1

Hormonal Interventions and Endocrine Axis in Prostate Cancer

CLASS OF DRUGS	DRUG NAMES	SITE OF ACTION	MECHANISM OF ACTION	COMMENTS
GnRH agonists	Leuprolide Goserelin Triptorelin	Pituitary gland	Stimulates release of LH; feedback loop ultimately decreases LH production	Mainstay of therapy for metastatic disease; leads to increase in FSH; considerable side effects
GnRH antagonists	Degarelix Abarelix Cetrorelix	Pituitary gland	Binds to receptors and blocks release of GnRH	Prevents testosterone surge; leads to decrease in FSH; considerable side effects
Adrenal-	Ketoconazole	Adrenal	Decreases	Selective CYP17

targeting drugs	Abiraterone Oreteronel (TAK-700) Galeterone	gland	androgen production from steroid precursors by blocking cytochrome P450 enzymes	inhibitors administered with low-dose prednisone; side effects can include hypertension, edema, and hypokalemia
First-generation AR antagonists	Flutamide Nilutamide Bicalutamide	Prostate Prostate cancer	Nonsteroidal antiandrogen inhibits binding of testosterone and DHT to the AR	Monotherapy not indicated; associated with gynecomastia
Second-generation AR antagonists	Enzalutamide Apalutamide	Prostate Prostate cancer	Blocks AR, minimizes nuclear translocation of AR, and diminishes AR-mediated transcription	Associated with falls, fatigue, and decreased appetite
5α-Reductase inhibitors	Finasteride (type II isoenzyme inhibition) Dutasteride (type I and II isoenzyme inhibition)	Prostate Prostate cancer	Inhibits the conversion of testosterone to DHT	Commonly administered for BPH; not indicated for prostate cancer management

AR, Androgen receptor; *BPH,* benign prostatic hyperplasia; *DHT,* dihydrotestosterone; *FSH,* follicle-stimulating hormone; *GnRH,* Gonadotropin-releasing hormone; *LH,* luteinizing hormone.

The initial paradigm of castration-resistance (previously termed “androgen-independent” or “hormone-refractory”) prostate cancer was, after blocking AR activity by removing ligand, prostate cancer cells would adapt by using non–AR-mediated resistance mechanisms to maintain cancer cell survival and drive proliferation. **Analyses of rapid/warm autopsies, however, of men succumbing to advanced CRPC demonstrated AR pathway activation is still necessary and sufficient for CRPC** (Rubin et al., 2000). Such studies thus refocused attention back to the AR as a key driver of CRPC. Moreover, such revelations led to a refinement of terminology from “androgen-dependent vs.

androgen-independent” to “castration-resistant” to reflect the continued dependency of CRPC on AR signaling (see Fig. 161.1) (Scher et al., 2004).

All current forms of hormonal therapy in prostate cancer function by reducing the ability of androgen to activate the AR, whether through lowering levels of androgen, decreasing conversion of testosterone to the more potent AR-ligand dihydrotestosterone, (DHT) or by blocking androgen-AR binding (see Table 161.1). A variety of molecular mechanisms are implicated in this process of castration-resistance (see Fig. 161.1). First, the AR gene is overexpressed in approximately 20% to 30% of CRPC metastases (Edwards et al., 2003; Koivisto et al., 1997), although more sensitive techniques such as gene expression profiling suggest amplification is more common when hormone-resistant human prostate cancer cell lines are compared with the hormone-sensitive tumors from which they were derived (Chen et al., 2004). Such alterations are thought to enhance the response of the cancer cell to low levels of endogenous androgens (Hyytinen et al., 2002; Mohler et al., 2004). Second, activating mutations in the AR gene have also been reported (Suzuki et al., 1996; Taplin et al., 1995). Mutations in the steroid-binding domain may alter ligand specificity, allowing other non-androgenic steroids as well as antiandrogens to bind and activate the mutant AR, even when the level of systemic androgen is fully suppressed. AR mutations have been most intensely studied in the context of the antiandrogen withdrawal response, in which acquired mutations in the AR are thought to result in a paradoxical stimulatory effect of antiandrogens on prostate tumor cells. Mutations in the ligand-binding domain of the AR have been detected in a small fraction of bone marrow specimens of men with castrate-resistant prostate cancer (Suzuki et al., 1996; Taplin et al., 1995, 2003a). In functional studies, these mutant receptors were stimulated rather than inhibited by some but not all antiandrogens. Third, other specific AR mutations and splice variants deleting the LBD provide an additional pathway for androgen escape in prostate cancer cells by producing AR variants that are no longer dependent on androgen ligand for activation (Antonarakis et al., 2014; Dehm et al., 2008). The predominant **androgen-receptor splice variant 7 (AR-V7)** has been strongly associated with castration resistance and overall poor patient survival (Antonarakis et al., 2014). Finally, non–AR-mediated pathways for maintaining cell survival or co-opting other steroid hormone receptors (such as the glucocorticoid receptor) have been shown to drive AR pathway–inhibited CRPC (Arora et al., 2013; Isikbay et al., 2014).

Key Points

- Steroid receptors, such as the AR, act as ligand-inducible transcription factors, containing three key functional domains: ligand binding, DNA binding, and transactivation.
- All current forms of hormonal therapy in prostate cancer reduce AR activity.
- Men succumbing to advanced CRPC continue to have AR pathway activation.
- Methods of AR pathway adaptation to hormonal therapy include mutation, amplification, de novo steroidogenesis, and AR splice variants.

Sources of Androgen

The hydrophobic properties of testosterone render it able to diffuse in and out of cells without any cellular transport machinery**. Cells that are primed to respond to testosterone (i.e., prostate, muscle) also express AR and the enzyme 5α-reductase.** Within the cellular cytosol, testosterone undergoes conversion to dihydrotestosterone (DHT) via the enzyme 5α-reductase. DHT binds and activates AR at approximately 13-fold that of testosterone and is the preferred ligand for AR (Wright et al., 1999). Engagement of AR by DHT results in translocation of AR into the nucleus, where it binds androgen response elements (AREs) in gene promoters to regulate gene expression (Chang et al., 2005; Heinlein and Chang, 2004).

Androgens produced by the adrenal gland are androstenedione and dehydroepiandrosterone (DHEA). Their production is stimulated by adrenocorticotropic hormone (ACTH), released by the pituitary gland in response to corticotropin-releasing factor. **Adrenal androgens are relatively weak compared with testosterone** and DHT and are insufficient to maintain prostate epithelium in castrated men (Walsh and Siiteri, 1975).

A final source of androgens is the induction of steroidogenesis by prostate cancer cells to produce their own AR ligands in an autocrine manner. In some instances, **tissue from prostate metastases has elevated androgens, and prostate cancer cells have increased the expression of steroidogenic enzymes necessary to synthesize androgens** (Montgomery et al., 2008). The discovery of alternative sources for androgen production, along with the improved understanding of adaptive changes within the AR that promote resistance to AR antagonists, have led to a new class of inhibitors to block steroid production as (discussed in the Inhibition of Androgen Synthesis section). The sources and relative potency of systemic androgens are summarized in Table 161.2.

TABLE 161.2

Major Circulating Androgens

SOURCE	ANDROGEN	AMOUNT PRODUCED/DAY (mg)	RELATIVE POTENCY	RELATIVE POTENCY/AM PRODUCED
Testes	Testosterone	6.6	100	15.2
Testes and peripheral tissues	Dihydrotestosterone	0.3	160–190	533–633
Adrenal glands	Androstenedione	1.4	39	27.9
Adrenal glands	Dehydroepiandrosterone	29	15	0.5

Key Points

- Cells responsive to testosterone express AR and the enzyme 5α-reductase, which converts testosterone (T) to DHT.
- Engagement of AR by DHT results in translocation of AR into the nucleus, where it binds AREs in gene promoters to regulate gene expression.
- Adrenal androgens are relatively weak compared with testosterone.

Mechanisms of Androgen Blockade

Four general approaches for androgen signaling blockade are currently available: (1) surgical removal of the testicles (orchiectomy), (2) AR antagonism, (3) inhibition of LHRH and/or LH, and (4) inhibition of androgen synthesis (see Table 161.1). Classically, ADT refers to chemical or surgical castration.

Orchiectomy

Because 95% of circulating testosterone originates from the testicles, bilateral orchiectomy quickly and dramatically reduces circulating testosterone levels to less than 50 ng/dL (1.7 nmol/L), which is considered within the castrate range. Within 6 hours of surgical castration, testosterone levels are within the castrate level (Maatman et al., 1985), and within 12 hours nearly all men have testosterone levels below 20 ng/dL (0.7 nmol/L) (Lin et al., 1994). Median testosterone levels after orchiectomy is 15 ng/dL (0.5 nmol/L) with all men achieving less than 30 ng/dL (1.0 nmol/L) (Oefelein et al., 2000). VACURG conducted a series of large clinical trials demonstrating the clinical effectiveness of surgical castration in reducing pain and improving performance status in men with advanced or metastatic disease (Byar, 1973; Byar and Corle, 1988). Subcapsular orchiectomy, with preservation of nonfunctional tissue, has been advocated as a technique of ADT that avoids the cosmetic and psychological consequences of a completely empty scrotum (Desmond et al., 1988). Because this approach relies on the complete removal of all intratesticular tissue and Leydig cells, it is more operator dependent than a simple orchiectomy. When a subcapsular orchiectomy is executed properly, the hormonal and cancer responses are indistinguishable from a simple, complete orchiectomy (Zhang et al., 1996). Although orchiectomy rather than chemical castration would lead to a dramatic decrease in US and worldwide health care costs, only 2% of men age 65 and older who started androgen deprivation between 2003 and 2005 had a simple orchiectomy (Shahinian et al., 2010). In a comparative population-based cohort, orchiectomy (compared with LHRH agonists) appeared to have significantly lower risks of cardiac events, peripheral arterial disease, and skeletal fractures (Sun et al., 2016). For those with prolonged therapy (≥35 months), lower rates of thromboembolism and diabetes were also observed.

Antiandrogens

Antiandrogens as a class of medications are molecularly AR antagonists. All antiandrogens in use currently rely on binding the AR's ligand-binding domain, resulting in competitive and allosteric inhibition of agonist ligand binding. There are steroidal antiandrogens such as cyproterone acetate that are no longer in clinical use, as well as early generation nonsteroidal antiandrogens (flutamide, bicalutamide, nilutamide), as well as the more potent third-generation antiandrogens enzalutamide, apalutamide, and darolutamide (the first two are FDA approved and in clinical use) (Crawford et al., 2018; Fizazi et al., 2017; Fig. 161.2).

FIG. 161.2 Chemical structures of steroidal and nonsteroidal antiandrogens. (Figure 3 from Crawford ED, Schellhammer PF, McLeod DG, et al.: Androgen receptor targeted treatments of prostate cancer: 35 years of progress with antiandrogen. *Urology* 200[5]:955–956, 2018 [online journal]: https://www.ncbi.nlm.nih.gov/pubmed/29730201.)

Steroidal First Generation

Cyproterone acetate, the classic steroidal antiandrogen with direct AR-blocking effects, also rapidly lowers testosterone levels by 70% to 80% through its progestational central inhibition of the androgen axis (Barradell and Faulds, 1994; Goldenberg and Bruchovsky, 1991; Jacobi et al., 1980). An oral agent, the recommended dose is 100 mg two to three times per day. Side effects are consistent with the hypogonadal state and include loss of libido, erectile dysfunction, and lethargy. Compared with an LHRH analog (goserelin acetate), cyproterone for men with metastatic prostate cancer was associated with shorter median time to clinical progression (Thorpe et al., 1996). An unblinded trial of 366 men randomized to intermittent versus continuous cyproterone acetate (100 mg PO three times daily) for men with prostate cancer metastatic to bone suggested quality-of-life advantages without meaningful differences in clinical progression or survival, although the sample size and power obviate definitive proof of oncologic equivalence (Verhagen et al., 2014). Severe cardiovascular complications (up to 10% of patients), gynecomastia (20%), and rare cases of fulminant hepatotoxicity can occur (Parys et al., 1991). For these reasons, it is rarely used, although it has been used at doses of 50 to 100 mg/day for the treatment of hot flashes (Goldenberg and Bruchovsky, 1991).

Nonsteroidal First- and Second-Generation

Considered early generation AR antagonists, traditional nonsteroidal antiandrogens (flutamide, nilutamide, bicalutamide) block AR activity but, when used as single agents, cause LH and testosterone levels to increase. Testosterone levels reach about 1.5 times the normal levels of hormonally intact men, allowing putative antiandrogen activity without inducing hypogonadism: potency therefore can be preserved (Brufsky et al., 1997). However, in clinical trials specifically examining erectile function and sexual activity in men on flutamide monotherapy, long-term preservation occurred in only 20% (Schroder et al., 2000). The peripheral aromatization of increased testosterone to estradiol commonly leads to gynecomastia and mastodynia with these agents (Knuth et al., 1984). Gastrointestinal toxicity, most notably diarrhea, is more common with flutamide than other nonsteroidal antiandrogens (Han and Nelson, 2000). Liver toxicity, ranging from reversible hepatitis to fulminant hepatic failure, is associated with all nonsteroidal antiandrogens and requires periodic monitoring of liver function tests (Thole et al., 2004). Interstitial pneumonitis with the possibility of progressing to pulmonary fibrosis has been associated with all available nonsteroidal antiandrogens (Bennett et al., 2002), the highest rate occurring with nilutamide (1% to 2% of patients) (Pfitzenmeyer et al., 1992).

Flutamide.

Flutamide was the first “pure” antiandrogen (Neri et al., 1967). Unlike the steroidal antiandrogens, there are no associated side effects of fluid retention or thromboembolism (Delaere and Van Thillo, 1991). In a randomized, double-blind study comparing flutamide with DES (3 mg/day) in metastatic prostate cancer, overall survival was significantly shorter with flutamide (28.5 months) compared with DES (43.2 months) (Chang et al., 1996). Because of the short half-life (6 hours) of the active metabolite, 2-hydroxyflutamide, this oral agent must be given three times a day at 250 mg per dose. For these reasons, it is rarely used in contemporary practice.

Bicalutamide.

A nonsteroidal antiandrogen with a long serum half-life (6 days), bicalutamide has a once-daily dosing schedule at 50 to 150 mg. It is the most potent of the “first-generation” nonsteroidal antiandrogens (Kolvenbag and Nash, 1999) and the best tolerated (Fradet, 2004; Kolvenbag and Blackledge, 1996; Schellhammer and Davis, 2004). The pharmacokinetics of bicalutamide are not affected by age, renal insufficiency, or moderate hepatic impairment (Mahler et al., 1998). As with other antiandrogens, bicalutamide is associated with maintenance of serum testosterone levels: in the majority of patients, these remain within the normal range (Denis and Mahler, 1996; Tay et al., 2004).

In a series of randomized trials, bicalutamide monotherapy at a 50 mg/day dose was inferior to medical or surgical castration for survival of men with metastatic disease (Bales Chodak, 1996; Kaisary et al., 1995; Kolvenbag and Nash, 1999). At a higher dose of 150 mg/day, bicalutamide monotherapy appeared to have equivalent efficacy to medical or surgical castration (Anderson, 2003; Iversen et al., 2000, 2004; McLeod et al., 2006; Tyrrell et al., 1998; Wirth et al., 2004) in men with locally advanced or metastatic disease. In these large phase III studies, bicalutamide monotherapy (150 mg/day) had significantly better quality of life in the domains of sexual interest and physical capacity (Iversen, 2003). There was, however, a high rate of gynecomastia (66%) and breast pain (73%) (Iversen, 2003). More concerning, in men with low-risk, localized prostate cancer, bicalutamide was associated with significantly worse overall survival compared with watchful waiting (Iversen et al., 2010). For these reasons, it was never widely adopted as monotherapy for men with clinically localized or metastatic prostate cancer.

Nilutamide.

The plasma half-life of nilutamide is 56 hours, and elimination is via hepatic clearance employing the cytochrome P450 system. Because steady-state plasma levels are achieved in 14 days with daily dosing (Creaven et al., 1991), dosing recommendations are a single 300-mg daily dose for the first month of treatment followed by a single 150-mg daily dose (Mahler et al., 1998). **About one-quarter of men on nilutamide therapy note a delayed adaptation to darkness after exposure to bright illumination** (Creaven et al., 1991). The early effects are usually reversible with cessation of nilutamide (Desai et al., 2001). Nilutamide is primarily of historical note and rarely used.

The first-generation antiandrogens are primarily used clinically for combined androgen blockade (CAB) with LHRH agonists. They have a definitive role in blocking the testosterone surge associated with initiation of LHRH agonists (see LHRH Agonist). Beyond the first approximately 30 days, during which the testosterone surge can be observed, long-term combined androgen blockade with an antiandrogen and chemical/surgical castration is discussed later under Combination Hormonal Therapy.

Nonsteroidal Second Generation

Enzalutamide.

This “second-generation” antagonist inhibits function by blocking the AR, inhibiting nuclear translocation and preventing DNA binding, and is a much more pharmacologically potent AR antagonist in comparison with first-generations antiandrogens such as bicalutamide (Tran et al., 2009). A phase III trial of enzalutamide (160 mg) in men with metastatic castration-resistant prostate cancer (mCRPC) who had failed docetaxel chemotherapy (AFFIRM) showed significant improvements in radiographic progression-free and overall survival, leading to FDA approval in 2012 (Scher et al., 2012). Similarly, another phase III trial in men with mCRPC who had not received chemotherapy (PREVAIL) also showed significant improvements in radiographic progression-free and overall survival (Beer and Tombal, 2014). Two randomized phase II study (TERRAIN, STRIVE) comparing enzalutamide with bicalutamide in a similar clinical state showed a significant improvement in median progression-free survival (15.7 vs. 5.8; 19.4 vs. 5.7 months) (Penson et al., 2016; Shore et al., 2016). Most recently, the phase III PROSPER trial of enzalutamide versus placebo in the nonmetastatic CRPC state showed a significant improvement in time to metastatic progression or death by nearly 2 years (36.6 vs. 14.7 months; hazard ratio (HR) = 0.29, $P < 0.001$) (Clegg et al., 2012; Hussain et al., 2018). Enzalutamide is now FDA approved across the entire spectrum of CRPC (nonmetastatic and metastatic, regardless of previous exposure to chemotherapy). The most common side effects of enzalutamide are fatigue, breast enlargement/tenderness, diarrhea, and hot flashes. Seizures were more common in men taking enzalutamide compared with placebo but occurred in less than 1%.

Apalutamide.

Apalutamide (ARN-509) is another "second-generation" AR antagonist without significant agonist activity that, like enzalutamide, potently inhibits AR nuclear localization, DNA binding, and androgen-mediated gene transcription within prostate cancer cells (Clegg et al., 2012). Safety and efficacy profiles in early stage clinical trials (Rathkopf et al., 2013; Smith et al., 2016) led to a large randomized Phase III trial (SPARTAN) of daily oral apalutamide (240 mg), which demonstrated a significant improvement in metastasis-free survival (40.5 vs. 16.2 months; HR = 0.28, $P < 0.001$) compared with placebo in men with nonmetastatic castrate-resistant prostate cancer with a PSA doubling time of 10 months or less (Smith et al., 2018). Consequently, it received FDA approval in 2018, for men with nonmetastatic castrate-resistant prostate cancer, irrespective of PSA doubling time. Approximately 25% of men experienced a rash, 12% experienced falls and fractures, and 8% had hypothyroidism.

Antiandrogen Withdrawal Syndrome

Patients treated with a combination of an antiandrogen and LHRH agonist can experience a decline in PSA and even objective responses after withdrawal of the antiandrogen from the combination. Based on this response, it appears the antiandrogen can paradoxically exert agonistic activity on prostate cancer cells. This phenomenon, first described with flutamide (Kelly and Scher, 1993), has now been demonstrated with all antiandrogens, including cyproterone acetate, as well as with DES and progestational agents (Kelly et al., 1997). Biologically, this phenomenon is believed to be secondary to adaptive mutations in the AR, which render the “antiandrogens” as AR agonists (Taplin et al., 1995, 2003b). Declines in PSA are seen within 4 weeks with flutamide withdrawal and within 6 weeks with bicalutamide and nilutamide withdrawal (Nieh, 1995). Between 15% and 30% of patients may have PSA declines of greater than 50% after antiandrogen withdrawal, and the declines have a median duration of 3½ to 5 months (Scher and Kelly, 1993; Small and Srinivas, 1995). The incidence of antiandrogen withdrawal syndrome (AAWS) with “second-generation” AR antagonists such as enzalutamide is considerably lower (0 to 10%), is also typically short-lived without objective radiographic responses, and presumptively is due to less AR agonist activity compared with “first-generation” AR antagonists (Rodriguez-Vida et al., 2015; von Klot et al., 2014). Overall survival has not been shown to be increased in those patients demonstrating AAWS (Small and Srinivas, 1995).

Inhibition of Luteinizing Hormone–Releasing Hormone

Luteinizing Hormone–Releasing Hormone Agonists

LHRH agonists (leuprolide, goserelin, triptorelin, histrelin) exploit the desensitization of LHRH receptors in the anterior pituitary after chronic exposure to LHRH, thereby decreasing production of LH, which subsequently leads to decreased production of testosterone. **The clinical utility of current LHRH agonists is based on synthesis of LHRH analogues by amino acid substitutions, particularly position 6 in the peptide, increasing their potency and half-lives.** Depot preparations and osmotic pump devices allow dosing intervals to extend from 28 days to 1 year, respectively, with a variety of intervening dosing options. **In a review of 24 trials involving more than 6600 patients, survival after therapy with an LHRH agonist was equivalent to orchiectomy** (Seidenfeld et al., 2000).

Initial exposure to LHRH agonists can result in a flare of LH and testosterone levels, resulting in a severe, life-threatening exacerbation of symptoms, almost exclusively occurring in men with metastases in the spine or weight-bearing regions (Waxman et al., 1985). The flare, associated with up to a 10-fold increase in LH, may last for 10 to 20 days (Weckermann and Harzmann, 2004). Fortunately, premedicating and co-administration of an antiandrogen functionally blocks the testosterone surge (Kuhn et al., 1989; Labrie et al., 1987;

Schulze and Senge, 1990). Although it had been argued the administration of the antiandrogen should precede the administration of the LHRH agonist by a week, others have found no differences in PSA levels with the simultaneous administration of both agents (Tsushima et al., 2001). Given the predictable length of the flare phenomenon, antiandrogen pre-administration or co-administration is required for only 21 to 28 days.

Luteinizing Hormone–Releasing Hormone Antagonists

LHRH antagonists (e.g., abarelix, cetrorelix, degarelix, ganirelix) bind immediately and competitively to LHRH receptors in the pituitary, reducing LH concentrations by 84% within 24 hours of administration (Weckermann and Harzmann, 2004). The direct antagonistic activity eliminates the LH and testosterone flare, which is a major therapeutic advantage of these agents: no need for antiandrogen pre-administration or co-administration. Eugonadal patients with impending spinal cord compression or severe bone pain for whom surgical castration is not appropriate may preferentially benefit from this class of agents.

In clinical trials of LHRH antagonist abarelix, testosterone levels dropped quickly, with 35%, 61%, and 98% of men chemically castrated at 2, 4, and 28 days, respectively (Tomera et al., 2001). Compared with an LHRH agonist and antiandrogen, abarelix was equally effective in achieving castrate levels of testosterone (Trachtenberg et al., 2002). Ninety-percent of men with symptomatic prostate cancer treated in an open-label fashion had improvements in pain and/or disease-related symptoms (Koch et al., 2003).

Many of the first- and second-generation antagonists induced significant histamine-mediated side effects, complications not observed as frequently in third- and fourth-generation agents (Weckermann and Harzmann, 2004). Nevertheless, **severe allergic reactions can occur with abarelix, even after previously uneventful treatment** (Koch et al., 2003). Abarelix is approved in the United States for the treatment of advanced prostate cancer in patients who cannot take other hormonal therapies and have refused surgical castration. Given the rare but serious allergic reactions, patients must be monitored for at least 30 minutes after administration.

Follicle-stimulating hormone (FSH) levels are only partially suppressed by LHRH agonists and are significantly elevated after surgical castration given the loss of inhibitory feedback. LHRH antagonists reduce LH and FSH levels (Lamharzi et al., 1998). In men with disease progression after surgical castration, treatment with abarelix reduced FSH levels by nearly 90% but did not meet criteria for PSA response (Beer et al., 2004). The clinical impact of lowering FSH levels is largely unknown.

Unlike abarelix, the LHRH antagonist degarelix has no known systemic allergic reactions (Gittelman et al., 2008; Klotz et al., 2008). In a phase III study, two separate dosing regimens of degarelix were compared with leuprolide (Klotz et al., 2008). At 3 days after administration, degarelix achieved testosterone levels of less than 50 ng/mL in more than 95% of patients, whereas leuprolide achieved this in 0 patients. Between months 1 and 12, testosterone was less than 50 ng/dL in 96% to 98% of men at all measurements, without significant difference between formulations or drug. Degarelix was more commonly associated with injection-site reactions and chills but had lower rates of urinary tract infection and arthralgia. Based on these non-inferior results, it was approved for use in the United States. **Pooled survival data from 5 prospective trials *suggest* biochemical, progression-free, and overall survival may be more favorable with degarelix compared with leuprolide or goserelin** (Klotz et al., 2014)**, although direct randomized comparison is lacking.**

Inhibition of Androgen Synthesis

Aminoglutethimide

Aminoglutethimide inhibits conversion of cholesterol to pregnenolone, an early step in steroidogenesis (Blankenstein and Bakker, 1985; Cash et al., 1967). **Given its inhibition of a very proximal step in adrenal function, aminoglutethimide blocks production of aldosterone and cortisol. As the medical version of a total adrenalectomy, the use of this agent requires replacement of cortisone and fludrocortisone.** Side effects include anorexia, nausea, skin rash, lethargy, vertigo, hypothyroidism, and nystagmus. Clinical responses have been observed in a subset of patients with castration-resistant prostate cancer treated with aminoglutethimide plus cortisone (Ponder et al., 1984; Sanford et al., 1976). In the PSA era, it is uncommonly used; however, treatment with aminoglutethimide (1000 mg/day) and hydrocortisone acetate (40 mg/day) resulted in a greater than 50% decline in PSA in 37% of patients, with median response times lasting 9 months (Kruit et al., 2004).

Ketoconazole

An orally active, broad-spectrum azole antifungal agent, ketoconazole is a nonselective P450-dependent pathway inhibitor. However, the principal mode of action intended for use in prostate cancer is blocking 17,20-desmolase, limiting the conversion of C_{21} to C_{19} steroids (e.g., DHEA-S and androstenedione). Based on the observation that some patients taking the drug developed gynecomastia, investigations of its effects on steroid synthesis demonstrated loss of adrenal steroid synthesis (Pont, 1987) and testosterone synthesis by Leydig cells (Ponder et al., 1984). The effects were rapid, with testosterone levels dropping to castrate level within 4 hours of administration in some cases (Trachtenberg et al., 1983). The effects were also immediately reversible, indicating dosing must be continuous (400 mg every 8 hours) to maintain low testosterone levels.

Early experience with ketoconazole in the treatment of prostate cancer showed it was tolerable, durable, and effective (Trachtenberg and Pont, 1984) and palliative for those who had failed first-line androgen ablation therapy (Pont, 1987). **Although ketoconazole is effective in rapidly bringing testosterone levels into the castrate range, with continuous treatment in the otherwise hormonally intact individual (no other surgical or chemical ADT), testosterone levels begin to rise and can reach low-normal ranges within 5 months of therapy** (Vanuytsel et al., 1987). Ketoconazole is uncommonly used subsequent to the development of more potent and selective androgen synthesis inhibitors, but it can be administered as a secondary hormonal manipulation in abiraterone-naive patients; although no improvement in survival, a randomized trial did show a higher rate of biochemical and objective responses when combined with antiandrogen withdrawal compared with antiandrogen withdrawal alone (Small et al., 2004). In addition to gynecomastia, ketoconazole is associated with lethargy, weakness, hepatic dysfunction, visual disturbance, and nausea (Scholz et al., 2005; Wilkinson and Chodak, 2004). Because of non-androgenic adrenal suppression, ketoconazole must be given with hydrocortisone (5–20 mg twice per day).

Abiraterone

Unlike ketoconazole, which inhibits several cytochrome P pathways, abiraterone is a potent and selective inhibitor of cytochrome P17 (CYP17), a key enzyme in androgen synthesis (Chang et al., 1996). Specifically, abiraterone inhibits 17α-hydroxylase and $C_{17,20}$-lyase, resulting in suppression of cortisol and androgen production (Fig. 161.3) but has the potential for a compensatory rise in ACTH leading to increased synthesis of aldosterone and its precursors.

Oestradiol

FIG. 161.3 Mechanism of action of abiraterone and potential side effects. *ACTH,* Adrenocorticotropic hormone.

Abiraterone was developed based on work showing castration-resistant prostate cancer remains androgen-responsive and remains driven by low levels of androgens. Toxicities stem from the effects of blocking the conversion of pregnenolone to 17-hydroxypregnenolone, resulting in an increase in the mineralocorticoids deoxycorticosterone and corticosterone (see Fig. 161.2). Untreated, this can result in hypokalemia, hypertension, and fluid overload (Attard et al., 2008). Co-administration of prednisone (5 mg one to two times daily) suppresses the ACTH increase and lowers the likelihood of mineralocorticoid excess. The seminal phase III trial of abiraterone was in men with metastatic castration-resistant prostate cancer after treatment with docetaxel (COU-AA-301 trial); abiraterone (1000 mg) plus prednisone significantly improved median progression-free (5.6 vs. 3.6 months) and overall survival (14.8 vs. 10.9 months) compared with placebo plus prednisone. Declines in PSA of 50% or more and radiographic responses occurred in 29% and 14% of men on abiraterone, respectively (de Bono et al., 2011). Similarly, in men with metastatic castration-resistant prostate cancer before chemotherapy (COU-AA-302 trial), abiraterone plus prednisone significantly improved median radiographic progression-free survival (16.5 vs. 8.3 months) and overall survival (not reached vs. 27.2 months) compared with placebo plus prednisone (Ryan et al., 2013). Most recently, **in men with newly diagnosed high-risk castrate-sensitive**

metastatic prostate cancer, a large Phase III trial (LATITUDE) was closed early when interim analysis showed abiraterone plus prednisone (plus maintenance of traditional ADT) was superior to traditional ADT by extending median radiographic progression-free (33.0 vs. 14.8 months) and overall survival (not reached vs 34.7 months, HR = 0.62) (Table 161.3; Fizazi et al., 2017**).**

TABLE 161.3

Landmark Phase III Clinical Trials in the Castration-Sensitive Biochemical Recurrent or Metastatic Setting

Key Points

- Androgen deprivation can be achieved by orchiectomy, inhibition of LH production, AR antagonism, or blocking androgen synthesis.
- Orchiectomy leads to an approximate 95% decrease in serum testosterone within 6 hours.
- Because of a multifaceted mechanism of action, newer generation AR antagonists have greater efficacy than early generation AR antagonists.
- Withdrawal of antiandrogens can lead to PSA decreases in some men but have not been associated with a survival advantage.
- LHRH antagonists eliminate testosterone flare seen with LHRH agonists.

Clinical Follow-Up on Hormonal Therapy

Depending on the indication for androgen blockade (M0 vs. M1, castrate-sensitive vs. castrate-resistant) and overall condition of the patient, monitoring frequency varies. For metastatic disease, clinical monitoring is typically performed every 3 months. Standard chemistries, blood counts as well as PSA should be performed at this interval, and testosterone can be added, especially before and initially after treatment changes. Standard imaging also varies based on symptoms, change in clinical state (i.e., from castrate-sensitive to castrate-resistant), and/or every 3 to 12 months.

Castrate level of testosterone (<50 ng/mL) should be maintained throughout ADT, a definition largely based on early serum testosterone assays relying on thin-layer chromatography and limited ability to measure very low levels (Oefelein et al., 2000). Since the introduction of radioimmunoassay (RIA), chemiluminescent, and mass spectrometry, accurate detection of significantly lower levels is possible. Trial data evaluating the addition of abiraterone along with data from 11 other studies (5 prospective and 6 retrospective) suggest a lower level of testosterone (even within the castrate range) may afford additional clinical benefit (Klotz et al., 2017). However, this has not been definitively shown in a prospective pre-specified manner, specifically whether early additive measures to further decrease testosterone levels are beneficial. If testosterone level has not achieved an appropriate nadir, consideration should be given to a different method of androgen deprivation (switching to a different LHRH agonist/antagonist; adding estrogen, an antiandrogen or biosynthesis inhibitor; or considering orchiectomy). In a small study of 8 patients with CRPC and a testosterone level between 20 and 50 ng/dL, switching from an LHRH agonist to antagonist led to 5 (63%) experiencing a PSA decline to less than 20 ng/dL (Soga et al., 2016). A continuously rising PSA with a sufficiently suppressed testosterone represents the emergence of castration resistance.

If there are concerns for clinical progression based on biochemical, symptomatic, or exam findings, traditional imaging typically includes chest (x-ray or CT), skeleton (bone scan), and abdomen/pelvis (CT or MRI). Consideration can also be given to newer molecular imaging modalities such as C choline, F fluciclovine, F sodium fluoride, prostate-specific membrane antigen (PSMA)–labeled imaging, Ga PET/CT or PET/MRI.

Response to Androgen Blockade

Prognostic Model

Based on 385 men from the GETUG-15 Phase III trial with castration-sensitive advanced prostate cancer (72% with metastases), clinical factors such as bone metastases and pain intensity and laboratory values such as alkaline phosphatase (ALP), hemoglobin, and LDH levels were directly related to prognosis (Gravis et al., 2015). Good-, intermediate-, and poor-risk categories (49%, 29%, and 22% of the population) were constructed with respective median overall survivals of 69, 47, and 37 months. **The strongest predictor for overall survival was ALP, a surrogate for volume of skeletal metastases.** This proposed model awaits validation in other cohorts and only considers laboratory values as “normal” versus “abnormal” rather than integration as continuous variables.

Prostate-Specific Antigen Metrics

After initiation of ADT, the majority of prostate cancer patients exhibit a clinical response: the magnitude and rapidity remain the best predictors of its durability. Assuming ADT effectively targets the androgen-sensitive population of prostate cancer cells, an incomplete or sluggish response is evidence of a significant castrate-resistant cell population.

Rapid PSA rise before starting ADT (PSA doubling time) has been independently associated with prostate cancer–specific mortality (D'Amico et al., 2005). For those destined to achieve an undetectable PSA (<0.2 ng/dL), shorter time from ADT initiation to undetectable PSA has been directly and independently correlated with improved cancer-specific mortality (D'Amico et al., 2007).

Among men with advanced or metastatic prostate cancer, the likelihood for progressing to castration-resistant disease within 24 months of starting ADT was nearly 15 times higher for patients who did not achieve an undetectable PSA (Benaim et al., 2002) and directly correlated to each interval increase in Gleason score (Benaim et al., 2002). In a cohort of Asian men, nadir PSA was the most accurate predictor of disease progression and independently associated with survival; achieving a PSA level of 1.1 ng/mL or less at 6 months after initiating ADT was directly correlated with progression at 2 years (Kwak et al., 2002). **In a significantly larger cohort of men with newly diagnosed metastatic prostate cancer started on ADT (*n* = 1345), 84% achieved a PSA less than 4**

ng/mL, 71% maintained a PSA less than 4 ng/mL at 7 months, and 45% maintained a PSA less than 0.2 ng/mL at 7 months. PSA after 7 months of ADT was a strong, independent predictor of survival (Hussain et al., 2009). Median survival was 75 months for men achieving a PSA nadir less than 0.2 ng/mL, 44 months for PSA between 0.2 and 4.0 ng/mL, and 13 months for more than 4 ng/mL. In a contemporary study randomizing men with metastatic castration-sensitive prostate cancer (mCSPC) to ADT with or without docetaxel, PSA less than 0.2 ng/mL at 7 months and low-volume metastases (no visceral metastases, 3 bone lesions or fewer, or at least 4 bone lesions limited to vertebral bodies and pelvis) were associated with prolonged survival, regardless of docetaxel administration, although docetaxel did increase the likelihood of achieving an undetectable nadir PSA (Harshman et al., 2018).

Other Clinical Predictors

Among men with a biochemical recurrence after local therapy and a PSA doubling time less than 6 months, higher Gleason score has been associated with time to cancer-specific mortality (Rodrigues et al., 2006). Among men with newly diagnosed metastatic prostate cancer starting ADT, performance status, bone pain, higher Gleason score, and PSA before initiating therapy were associated with survival (Hussain et al., 2006).

Bone Scan Index

Bone scan index (BSI), an automated method of estimating the percentage of skeleton with metastatic disease, has been directly and independently associated with time from castration-sensitive prostate cancer to castration resistance (Poulsen et al., 2016; Zacho et al., 2017). A BSI of more than 1% is considered an adverse prognostic feature. In a pre-specified analysis of 721 men with metastatic CRPC who had not received chemotherapy, BSI was independently associated with time to opiate use, symptomatic progression, and overall survival (Armstrong et al., 2018). The median overall survivals by BSI quartile (0.05%, 0.58%, 2.06%, 6.72%) were 34.7, 27.3, 21.7, and 13.3 months, respectively. However, BSI is not routinely performed in clinical practice.

Genomic Predictors

In addition to clinical predictors of response to hormonal therapies in prostate cancer, the growing field of genomic biomarkers is gaining relevance in prostate cancer. HSD3B1 is a steroidogenic enzyme that encodes for 3β-hydroxysteroid dehydrogenase-1 (3βHSD1), primarily responsible for converting adrenal androgens into DHT. A specific acquired mutation in HSD3B1 (nucleotide polymorphism 1245A>C), but also present via germline single nucleotide polymorphism in 15% to 35% of men, causes 3βHSD1 resistance to degradation, increased conversion of androgen from extragonadal sources, and excessive intratumoral DHT. In a multicohort study of men receiving ADT for biochemical recurrence after radical prostatectomy, progression-free survival, metastasis-free, and overall survival decreased as the number of variant HSD3B1 alleles increased (Hearn et al., 2016). Median PFS after starting ADT among homozygous wild-type, heterozygous, and homozygous variant men were 6.6, 4.1, and 2.5 years, respectively, and median MFS was 9.1, 6.8, and 3.6 years, respectively. Inheritance of two variant HSD3B1 alleles was independently associated with progression-free, metastasis-free, and overall survival. This provocative finding has been independently replicated and validated for progression-free survival in another cohort (Whitley et al., 1987).

Similar observations were seen in a cohort of men treated with ADT for biochemical failure after radiation therapy (Hearn et al., 2018) with median time to metastases for wild-type, heterozygous, or homozygous variant alleles being 7.4, 5.8, and 4.4 years, respectively. On multivariable analysis, presence of 2 variant HSD3B1 alleles (homozygous variant) was associated with a twofold increased rate of metastases (HR = 2.01, 95% CI 1.02 – 3.97, $P = 0.045$). **Collectively, the data suggest germline HSD3B1 variants are a predictive biomarker for response and ultimate resistance to ADT.** A clinical grade test for HSD3B1 is not yet available.

Key Points

- After androgen blockade, the rapidity and magnitude of PSA decrease are associated with duration and efficacy of response.
- HSD3B1 converts adrenal androgens into DHT, and variant alleles are associated with less favorable responses to ADT.
- In castration-sensitive prostate cancer, treatment response is associated with bone metastases, symptoms, and serum ALP, hemoglobin, and LDH levels.

General Complications of Androgen Ablation

Osteoporosis

Androgen ablation predisposes to loss of bone mineral density (BMD) with subsequent osteopenia and osteoporosis. Fragile bones increase the risk of skeletal fracture. Before the initiation of ADT, more than half of older men meet BMD criteria for osteopenia or osteoporosis—defined as more than 2.5 standard deviations below an age-specific reference mean (Conde et al., 2004; Wei et al., 1999). In men with nonmetastatic prostate cancer on ADT, population-based assessments have suggested a 20% to 45% increased risk of fracture compared with a control group (Smith et al., 2005, 2006).

The longer a man remains on ADT, the greater the risk of fracture (Daniell et al., 2000; Krupski et al., 2004). After 5 years on ADT, 19% of men experienced fractures compared with 13% of controls (Shahinian et al., 2005); over 15 years the cumulative incidence of fractures was 40% compared with 19% in non-castrate controls (Melton et al., 2003).

Treatment of osteoporosis begins with recognition. BMD of the hip as measured by dual-energy x-ray absorptiometry (DEXA) should be considered for all men who are anticipated to be on long-term ADT (Bae and Stein, 2004; Diamond et al., 2004). Fracture risk can be assessed using FRAX, an assessment tool provided by the World Health Organization (WHO) (Kanis et al., 2007). BMD testing among men receiving ADT is low in multiple practice settings, such as the Veterans Administration (15%) and among men in SEER-Medicare (10%) (Kirk et al., 2018; Morgans et al., 2013).

To mitigate risk of fracture, all men starting ADT (regardless of fracture risk) should ensure adequate intake of calcium and vitamin D_3, engage in regular weight-bearing exercise, and be encouraged to quit smoking tobacco. The NCCN Guidelines Panel derives its recommendation from the National Osteoporosis Foundation: calcium 1000 to 1200 mg/daily and vitamin D3 400 to 1000 IU/daily for all men with additional measures for men with low bone mass (T-score between −1.0 and −2.5 at the femoral neck, total hip, or lumbar spine by DEXA) and 10-year probability of hip fracture exceeding 3% or major fracture exceeding 20%. Secondary preventive measures include denosumab (60 mg SQ every 6 months), zoledronic acid (4–5 mg IV annually), or alendronate (70 mg PO weekly). For men on these medications, a follow-up DEXA scan is recommended 1 year after treatment to assess response. In all other clinical scenarios, there are no specific guidelines on value and frequency of bone health monitoring via calcium or vitamin D levels or DEXA scan.

Hot Flashes

Described as a subjective feeling of warmth in the upper torso and head followed by objective perspiration, hot flashes (alternatively referred to as hot flushes or vasomotor symptoms) are among the most common side effects of patients undergoing androgen ablation, affecting between 50% and 80% (Moyad, 2002; Nishiyama et al., 2004; Spetz et al., 2003). Occurring spontaneously and precipitated by changes in body position, ingestion of hot liquids, or changes in environmental temperature, the exact cause of hot flashes remains undefined. The proposed mechanisms have included increases in hypothalamic adrenergic concentrations and alterations in β-endorphins and calcitonin gene–related peptides acting on the thermoregulatory center in the hypothalamus (Yuzurihara et al., 2003). Hot flashes generally decrease in frequency and intensity over time but can persist in some men (Holzbeierlein et al., 2004).

Treatment of hot flashes should be reserved for those men who find them particularly bothersome. In a double-blind, placebo-controlled crossover study, the progestational agent megestrol acetate (20 mg twice per day) significantly reduced the frequency of hot flashes (Loprinzi et al., 1994). The dose can be reduced to 5 mg twice daily, which may help reduce the appetite-stimulating effect of this agent. The efficacy of cyproterone acetate in counteracting hot flashes is based on its progestational effects (Cervenakov et al., 2000). Dosing should start at 50 mg/day and can be titrated to 300 mg/day. Estrogenic compounds such as low-dose DES and transdermal estradiol appear to be the most effective treatment, with up to 90% partial or complete resolution of symptoms (Gerber et al., 2000; Miller et al., 1992; Smith, 1994). However, high rates of gynecomastia and thromboembolic effects have limited their use. **In a phase III randomized, double-blind, placebo-controlled trial, the highest studied dose of gabapentin (900 mg) decreased hot flashes to a moderate degree** (Loprinzi et al., 2009).

Antidepressant agents, particularly the selective serotonin reuptake inhibitor venlafaxine (12.5 mg twice daily), have reduced hot flashes in more than 50% of men (Loprinzi et al., 2004; Quella et al., 1999). **A randomized trial of 311 men on ADT with hot flashes evaluated venlafaxine (75 mg/daily), medroxyprogesterone acetate (20 mg/daily), and cyproterone acetate (100 mg/daily), suggesting benefit for all but superiority to medroxyprogesterone and cyproterone** (Irani et al., 2010).

Clonidine, a centrally acting α agonist that decreases vascular reactivity, has previously been used; however, in a small placebo-controlled study of 70 men, transdermal clonidine did not significantly decrease hot flashes (Loprinzi et al., 1994). Acupuncture has been evaluated in single-arm designs with encouraging results and is worthy of further study but has not been subjected to placebo-controlled trials (Ashamalla et al., 2011; Harding et al., 2009). Soy protein has been proposed as a remedy but failed to decrease hot flash symptom severity score in a randomized trial (Vitolins et al., 2013). A small randomized trial evaluated cognitive behavioral therapy compared with standard treatment and showed a decrease in hot flash frequency and intensity at 6 weeks, which was not maintained at 32 weeks (Stefanopoulou et al., 2015). In sum, medications such as progestins have a role in treating hot flashes; however, side effects must be balanced, and thus their use is typically reserved for hot flashes that significantly interrupt quality of life.

Sexual Dysfunction (Erectile Dysfunction and Loss of Libido)

The effects of ADT on sexual function are profound, as first described by Huggins (1941): “Sexual desire and penile erections were absent in all cases following castration.” **Loss of sexual functioning is not inevitable.** Specifically, between 10% and 17% of men undergoing ADT can maintain an erection adequate for intercourse (Potosky et al., 2001; Tomic, 1983). **Libido is more severely compromised, with only 5% of men maintaining a high level of sexual interest after ADT** (Potosky et al., 2001). Loss of penile volume, decreasing penile length, and loss of nocturnal penile tumescence are common (Higano, 2003; Marumo et al., 1999).

Treatment for loss of libido is extremely difficult—if not impossible—for those on ADT. Oral phosphodiesterase-5 inhibitors (e.g., sildenafil, vardenafil, tadalafil) typically are not effective, but treatments such as intraurethral suppositories, vacuum erection devices, intracavernosal injections, or placement of an inflatable penile prosthesis can be effective in selected patients. A study evaluated the role of an exercise program in 57 men on ADT. After 12 weeks, the exercise group reported a higher percentage of men reporting a major interest in sex (17% vs. 0, *P* = 0.024) (Cormie et al., 2013).

Cognitive Function

Neuropsychological testing in men ages 50 to 91 and followed for an average of 10 years showed hypogonadism led to worse memory, worse visuospatial performance, and a faster rate of decline in visual memory with no impact observed for measures of verbal knowledge, mental status, or depressive symptoms (Moffat et al., 2002). In a study of 82 men with prostate cancer randomized to LHRH agonist, cyproterone, or observation, 50% of men with androgen deprivation experienced significant cognitive decline at 6 months, specifically in tasks requiring complex information processing, compared with no men under observation (Green et al., 2002, 2004). However, a larger case-control study of 241 men (prostate cancer with ADT, prostate cancer without ADT, and healthy controls) undergoing 14 neuropsychological tests did not show a meaningful decline in cognitive function associated with ADT at 6, 12, or 36 months (Alibhai et al., 2010a, 2017).

In a small study of men on ADT and functional MRI, there was reduced activation in the right parieto-occipital region when involving manipulation and spatial information (Cherrier et al., 2010). There have been reports of an association between ADT and dementia (Alzheimer and non-Alzheimer), although most studies are methodologically suboptimal, and there are studies supporting and refuting the association (Baik et al., 2017; McHugh et al., 2018; Nead et al., 2017).

Changes in Body Habitus

As noted by Huggins (1941) and colleagues, ADT is associated with an increase in appetite, and low testosterone is associated with increased insulin levels and abdominal girth (Seidell et al., 1990). A loss of muscle mass and increase in percent fat are common in men undergoing ADT, and these changes are most pronounced after initiation of ADT (van Londen et al., 2008). After 1 year of ADT, the mean overall weight increases by 1.8% to 3.8%, which translates into about 5 lb for a 200-lb man (Berruti et al., 2002; Smith, 2004; Smith et al., 2002). Another study found significantly more weight increase: a median of 6 kg (13.2 lb) (Higano et al., 1996). Lean body mass usually decreases (sarcopenia), with average loss of 1.0%, 2.1%, and 2.4% at 1, 2, and 3 years, respectively, after initiating ADT (Smith et al., 2012). Weight gain is largely due to an increase in fat mass (Levy et al., 2008). The average increase in fat mass ranges from 9.4% to 23.8% (Berruti et al., 2002; Smith, 2004; Smith et al., 2002). In a study evaluating 259 men, nearly evenly split among those with prostate cancer on ADT versus men with prostate cancer not on ADT versus healthy controls, there was also a significant decrease in endurance (as measured by a 6-minute walk test) and grip strength evident within 3 months of starting ADT (Alibhai et al., 2010b, 2017).

Diabetes and Metabolic Syndrome

Given the aforementioned changes in body habitus, it is not surprising that metabolic syndrome, a clustering of specific cardiovascular disease risk factors related to insulin resistance, is present in more than 50% of men undergoing long-term ADT (Braga-Basaria et al., 2006). Unlike classic metabolic syndrome characterized by visceral fat accumulation, ADT preferentially increases subcutaneous fat and leads to an increase of high-density lipoprotein (HDL) cholesterol concentrations (Smith et al., 2008). In a small, but carefully controlled prospective study, ADT significantly decreased insulin sensitivity in men with prostate cancer (Smith et al., 2006). These findings were supported by a very large observational study (73,196 men with prostate cancer) in which there was a significant risk of developing diabetes with a GnRH agonist (adjusted HR; 1.44, $P < 0.001$) or orchiectomy (adjusted HR; 1.34, $P < 0.001$) (Keating et al., 2006), findings subsequently replicated among 37,000 men within the Veterans Healthcare Administration (Keating et al., 2010). In addition, for men with diabetes starting ADT, there appears to be a higher likelihood of needing additional diabetes medications and worsening of HgA1c levels (Keating et al., 2014).

Cardiovascular Morbidity and Mortality

Given the generally adverse effects of ADT on body habitus, glucose metabolism, and lipid profiles, it is not surprising ADT is associated with increased cardiovascular morbidity and mortality. The effects appear to be most pronounced in men with lower-risk prostate cancer treated with ADT. In a large (22,816 subjects) population-based registry, newly diagnosed prostate cancer patients who received ADT for at least 1 year had a 20% higher risk of cardiovascular morbidity compared with similar men who did not receive ADT (Saigal et al., 2007). In men over age 65 undergoing radical prostatectomy who also received ADT, the cumulative incidence of cardiovascular death was 5.5% over 5 years compared with 2.0% in those not receiving ADT (Tsai et al., 2007). In contrast, in men with locally advanced prostate cancer treated with radiation therapy and ADT, there was not an increase in cardiovascular mortality compared with men receiving radiation therapy alone (Efstathiou et al., 2008). In a very large population-based cohort of men receiving androgen deprivation, a GnRH agonist was associated with an increased risk of coronary artery disease (adjusted HR 1.16, $P < 0.001$), myocardial infarction (adjusted HR 1.11, $P = 0.03$), and sudden cardiac death (adjusted HR 1.16, $P = 0.04$) (Keating et al., 2006). Among 182,000 men age 66 or older with nonmetastatic prostate cancer on ADT, risk of peripheral artery disease and venous thromboembolism were increased (Hu et al., 2012).

Gynecomastia

Depending on the agents used in ADT, alterations in breast tissue are common. Gynecomastia (an increase in breast tissue) and mastodynia (breast tenderness) may occur together or independently. In a randomized trial of leuprolide versus DES, rates of gynecomastia/breast tenderness were reported in 3% versus 49% of men, respectively (Leuprolide Study G, 1984). Other series have suggested rates of 13% to 16% with leuprolide (Crawford et al., 1989; Rizzo et al., 1990). Rates of gynecomastia with or without mastodynia in men undergoing bilateral orchiectomy or using GnRH agonists are approximately 5% or less (Dobs and Darkes, 2005). Likewise, the peripheral conversion of testosterone to estradiol associated with the antiandrogens induces gynecomastia and/or mastodynia in approximately half of all men taking bicalutamide at 150 mg (See et al., 2002; Wirth et al., 2001) or enzalutamide.

Prophylactic radiation therapy (10–15 Gy, single fraction) has been used to prevent or reduce painful gynecomastia (Tyrrell et al., 2004; Widmark et al., 2003) as a result of DES or antiandrogen therapy. Radiation has no benefit once gynecomastia has begun. Liposuction and subcutaneous endoscopic-assisted mastectomy have been used to treat established gynecomastia (Higano, 2003). The selective estrogen receptor modulator tamoxifen (20 mg/day) has been successfully used to reduce rates of gynecomastia/mastodynia in men being treated with antiandrogen monotherapy (Autorino et al., 2006), but its use is non-standard.

Anemia

The anemia associated with ADT is normochromic, normocytic, and very common: 90% of men receiving combined androgen blockade experience declines in hemoglobin concentration of at least 10% (Strum et al., 1997). In a population-based UK cohort of 10,000 men with nonmetastatic prostate cancer, ADT was associated with an approximately threefold increased rate of anemia, present within 6 months of initiating treatment and chronic in duration (Hicks et al., 2017). In men undergoing orchiectomy, 78% had a median hemoglobin decrease of 1 g/dL or more (Fonseca et al., 1998). Although anemia can be further complicated by tumor growth in the marrow space, compromising hematopoiesis, even men with nonmetastatic prostate cancer experience anemia with ADT (Choo et al., 2005). Unfortunately, anemia (defined as hemoglobin <12 g/dL) is associated with a shorter survival in those patients who were anemic before initiation of ADT (Beer et al., 2004). Compensatory mechanisms limit the symptomatic effects of anemia to a small subset (13%) of men (Strum et al., 1997). The anemia is reversible after stopping ADT, but this may take up to a year (Strum et al., 1997).

Key Points

- Androgen deprivation–based therapies for prostate cancer are associated with cumulative bone mineral density loss, and patients should have regular bone mineral density examinations, take calcium/vitamin D supplements, and be considered for bone-strengthening agents.
- ADT commonly causes increased adiposity, and prolonged exposure is associated with an increased risk of developing metabolic syndrome, diabetes mellitus, and cardiovascular disease.
- There are data to suggest that long-term androgen deprivation may lead to changes in cognition and memory function; however, the data are somewhat conflicting.

Combination Therapy

The advent of nonsurgical, reversible hormone therapy coupled with its profound effects on prostate cancer have led to broad investigations of the combination of ADT with nearly every other treatment applied to prostate cancer. In some cases, most notably external beam radiotherapy and chemotherapy, the combination clearly improves the outcomes; in others, most notably radical prostatectomy, there is no apparent benefit.

With Radical Prostatectomy

Early clinical studies combining hormonal therapy before surgery (neoadjuvant) were promising. In nonrandomized clinical trials of ADT (chemical castration) before radical prostatectomy, the effects on the final surgical specimen were dramatic. Positive surgical margin rates fell from nearly 50% in hormonal intact patients to 15% in ADT patients (Lee et al., 1997). There was a nonsignificant trend toward improved biochemical outcome with neoadjuvant ADT. Based on these findings and a perception that neoadjuvant ADT reduced blood loss and rendered the procedure easier to perform, three randomized prospective studies compared 3 months of ADT followed by radical retropubic prostatectomy (RRP) to RRP alone (Klotz et al., 2003; Soloway et al., 2002; Witjes et al., 1997). With adequate follow-up, there was no significant difference in PSA progression between the groups. The lack of improved biochemical recurrence in these three randomized prospective trials using 3 months of neoadjuvant ADT before RRP argues this combination is not standard in the treatment of prostate cancer. Further studies of different duration of hormonal and with more potent hormonal agents are ongoing.

With Radiation Therapy

Unlike the lack of long-term improved cancer-specific progression with the combination of ADT and radical prostatectomy, several phase III clinical trials have shown a benefit with the combination of ADT and external beam radiation in overall survival, cancer-specific survival, and freedom from disease progression. The benefit appears to be in men with locally advanced disease and/or those with high-grade, high-risk disease.

In brief, there are several landmark trials that established a role for ADT in conjunction with radiation for prostate cancer. A phase III study comparing radiation alone to the combination of radiation and orchiectomy in men undergoing pelvic lymph node dissection was closed because of a high frequency of progression in the radiation-only arm (Granfors et al., 1998). At a median 9.3 years of follow-up, a significant difference in clinical progression (61% vs. 31%), overall mortality (61% vs. 38%), and prostate cancer–specific mortality (44% vs. 27%) favored radiation and orchiectomy versus radiation alone (Granfors et al., 1998). These observations were supported by another study randomizing men with locally advanced prostate cancer to radiation alone versus radiation combined with goserelin for 3 years (Bolla et al., 1997). With long-term follow-up, there was a dramatic improvement in progression-free survival (HR = 0.42, $P < 0.0001$) and overall survival (HR = 0.6, $P = 0.0004$) (Bolla et al., 2010). **Clearly, in locally advanced, high-risk disease, the combination of radiation therapy with ADT is better than radiation alone.** Furthermore, the duration of ADT matters. In the RTOG 92-02 study, 4 months of concurrent ADT+RT followed by 24 months of ADT versus the concurrent 4 months alone demonstrated a significant improvement in disease-specific survival and showed an improvement in overall survival for the highest risk (Gleason score 8 and above) individuals (Horwitz et al., 2008).

Combination Hormonal Therapy

Among all the efforts to improve the efficacy of ADT, none has been as widely studied as combinations of the various forms of hormone therapy, particularly if mechanistically nonredundant. For example, ablation of the source of androgen (castration) coupled with inhibition of LHRH with DES was one of the first combinations studied clinically to suggest improved survival (Nesbit and Baum, 1951); upon closer scrutiny of the first VACURG study, the survival advantage of this combination was lost (Blackard et al., 1973). Likewise, an early experience with an LHRH analogue and a first-generation antiandrogen in 30 patients suggested improved outcomes compared with standard treatment (Labrie et al., 1983). A meta-analysis of 27 prospective, randomized, international clinical trials of the combination of first-generation antiandrogens with either castration or an LHRH agonist (referred to as “combined androgen blockade, or CAB”) has been performed to coalesce disparate findings between trials. In the meta-analysis, 5-year survival with CAB was 25.4% compared with

23.6% with standard ADT, a nonsignificant gain in favor of CAB of 1.8%. Studies including the steroidal antiandrogen cyproterone acetate had a slightly worse outcome on the CAB arms (5-year survival 15.4% vs. 18.1% for ADT alone), suggesting increased non–prostate cancer deaths or inferior cancer-specific activity in those receiving cyproterone acetate. When studies examining the outcomes of the nonsteroidal antiandrogens flutamide or nilutamide were considered independent of those with cyproterone acetate, the 5-year survival improved from 24.7% (standard ADT) to 27.6% for CAB. This 2.9% improvement was significant, but the meta-analysis had a 0 to 5% range of uncertainty about the true size of the benefit; therefore the magnitude of this benefit is of unclear clinical relevance**.**

The idea of trying to eliminate all sources of endogenous androgen (testicular and adrenal) in treating prostate cancer is not new: bilateral surgical adrenalectomy was performed with failure far outweighing success (Huggins and Scott, 1945). Although the blockade of androgen signaling with classic combined androgen blockade has largely resulted in a nonsignificant improvement in outcomes, the advent of more potent hormone signaling inhibitors is changing the paradigm of hormonal treatment for metastatic prostate cancer. Specifically, the adrenal androgen synthesis abiraterone acetate (see Fig. 161.2) has been combined with chemical/surgical castration for metastatic castration-sensitive prostate cancer (mCSPC). In a landmark phase III study of abiraterone+ADT for patients with mCSPC with high-risk disease (defined as having at least two high-risk features: Gleason score 8 or higher, at least three bone metastases, visceral disease) showed a significant improvement in overall survival (HR = 0.62, $P < 0.0001$) with the addition of abiraterone. All secondary end points, including time to pain progression, initiation of chemotherapy, symptomatic skeletal events, and PSA progression also favored the abiraterone arm (Fizazi et al., 2017). Confirming these results, the abiraterone+ADT arm of the STAMPEDE trial, which had looser inclusion criteria allowing advanced CSPC (52% metastatic, 28% node-negative localized, 20% node-positive localized), showed a near identical improvement in overall survival (HR = 0.63, $P < 0.001$) (James et al., 2017). **These two trials have solidified the inclusion of abiraterone to ADT as a standard of care for mCSPC (see Table 161.3).**

With Chemotherapy

Docetaxel chemotherapy has established, but modest, efficacy for the treatment of metastatic castration-resistant prostate cancer (mCRPC) (Tannock et al., 2004). Based on the improvement in overall survival seen with docetaxel in mCRPC, several phase III trials combined docetaxel with first-line castration-based hormonal therapy for the treatment of mCSPC (see Table 161.3). The GETUG-AFU15 trial compared up to 9 cycles of standard dosed docetaxel (75 mg/m^2 every 21 days) with ADT versus ADT alone and showed no improvement in overall survival, although progression-free survival was improved (Gravis et al., 2013, 2016). However, two subsequent large prospective phase III studies have shown an improvement in overall survival. The E2805 CHAARTED study randomized 790 patients to receive 6 cycles of standard docetaxel+ADT versus ADT alone and showed a significant improvement in overall survival (HR = 0.61, $P < 0.001$). This improvement was driven by the patients with high-volume disease (four or more bone metastases and/or visceral disease) in whom there was an 18-month (49.2 vs. 32.2 months) improvement in median overall survival (Sweeney et al., 2015). The docetaxel arm of the STAMPEDE trial also showed an improvement in overall survival with the addition of docetaxel to long-term ADT (HR = 0.78, $P < 0.06$) (James et al., 2015). A meta-analysis of the randomized phase III studies was performed and concluded a legitimate survival advantage for the addition of docetaxel to first-line ADT for mCSPC (The Medical Research Council Prostate Cancer Working Party Investigators Group, 1997).

Key Points

- There is no proven role for presurgical hormonal therapy in combination with surgery; however, for patients with node-positive disease at prostatectomy, androgen deprivation can be considered.
- Androgen deprivation therapy concurrent with and after radiation is the standard of care for high-risk localized disease getting treated with radiation.
- Potent combination hormonal therapy with abiraterone acetate and standard medical or surgical castration is a standard of care for castration-sensitive metastatic prostate cancer.
- For patients with high-volume metastatic castration-sensitive prostate cancer, docetaxel chemotherapy with androgen deprivation therapy is also a

standard of care.

Timing of Therapy

The timing of the initiation of ADT is a somewhat controversial area of prostate cancer management. The spectrum of opinions ranges from primary ADT at time of diagnosis to the initiation of ADT at the first sign of primary prostate cancer failure (early) to initiation of ADT only with objective evidence of distant metastatic disease (late) (Loblaw et al., 2004; Miyamoto et al., 2004; Reese, 2000; Sharifi et al., 2005; Walsh et al., 2001). There is no question that early ADT delays biochemical and clinical disease progression, but the effects of early ADT on survival remain unclear (Ryan and Small, 2005). For the sake of this discussion, ADT will be considered continuous, from initiation until death; intermittent ADT is discussed in a subsequent section. Likewise, this discussion focuses on overall and prostate cancer–specific survival resulting from ADT. The morbidity from ADT also must be integrated into clinical decision-making.

Continuous Androgen Deprivation Therapy: Immediate Versus Delayed

Debates about the timing of ADT are not new. In 1973 the results of a large (more than 1900 men) study performed in the Veterans Administration of early versus late hormonal therapy for prostate cancer, across a spectrum of disease states, were reported (Byar, 1973). In men with metastatic disease, death from prostate cancer occurred in 48% of those treated early versus 47% of those treated late. In men with locally advanced disease, death from prostate cancer occurred in 14% of those treated early versus 17% of those treated late. Since that time, several randomized studies have applied ADT at different times in the natural history of prostate cancer; the results of those studies must be considered within the context of when ADT is used and the circumstances of the study.

Results in Clinically Localized Disease

In the bicalutamide Early Prostate Cancer program, men were randomized to bicalutamide 150 mg or placebo in addition to standard care (See et al., 2003). End points of these trials included overall survival, progression-free survival, and tolerability. In the subset of men with clinically localized disease, the overall survival was significantly *worse* in those undergoing ADT with bicalutamide

150 mg compared with placebo (Iversen et al., 2004). No specific cause for this decline in overall survival with ADT was identified, but it appeared to be the result of increased deaths from non–prostate cancer causes for those on bicalutamide.

A large study of 19,271 men 66 years or older with localized prostate cancer who did not receive definitive local therapy found that primary ADT was associated with lower 10-year prostate cancer–specific survival compared with those on conservative management (Lu-Yao et al., 2008). Although this finding could be the result of more aggressive prostate cancers requiring immediate primary ADT, there was no increase in 10-year overall survival with primary ADT. The authors concluded “primary ADT is not associated with improved survival in the majority of elderly men with localized prostate cancer when compared with conservative management” (Lu-Yao et al., 2008). Finally, in a retrospective, matched cohort study of patients who received adjuvant ADT (within 90 days of node-negative, radical prostatectomy) compared with those who did not, there was a 3% improved prostate cancer–specific survival (98% vs. 95%, respectively, $P = 0.009$) but no improvement in overall survival (83% in both groups) (Siddiqui et al., 2008).

Primary ADT—defined as the administration of ADT to men without metastases as sole therapy at the time of diagnosis—has previously been widespread, particularly in men more than 65 years old: in one study, up to 40% of these men received primary ADT (Shahinian et al., 2006). A retrospective cohort study from three integrated health care plans found that primary ADT did not alter the risk of all-cause mortality nor risk of prostate cancer–specific mortality (Potosky et al., 2014). Primary ADT was associated with decreased risk of all-cause mortality only in men with high risk of prostate cancer progression. There has been a prospective, randomized study conducted by the European Organisation for the Research and Treatment of Cancer trial of immediate versus delayed ADT in pN1-3M0 patients without local treatment of the primary tumor; 302 men were randomized to delayed ADT ($n = 115$) or immediate ADT ($n = 119$), with a primary end point aimed at proving noninferiority of delayed ADT. At final analysis, with a median follow-up of 13 years, the median overall survival in the immediate ADT group was 7.6 years (95% CI 6.3–8.3 years) versus 6.1 years (95% CI 5.7–7.3 years) in the delayed ADT group. The 10-year cumulative incidence of death from prostate cancer was 55.6% in the delayed ADT group versus 52.1% in the immediate ADT group, and noninferiority was not established (Schroder et al., 2009). The study was not designed or powered to show superiority of immediate ADT. **In sum, primary ADT does not provide a survival benefit for most men with clinically localized prostate cancer but may for those with high-risk disease**.

Results in Lymph Node Metastatic Prostate Cancer as Adjuvant Therapy

A randomized prospective study of immediate ADT compared with delayed ADT was performed by the Eastern Cooperative Oncology Group (ECOG) in men with histologic evidence of metastatic prostate cancer in regional lymph nodes after radical prostatectomy. At the time of the initial report, at 7.1 years of median follow-up, overall survival significantly ($P < 0.02$) favored the immediate ADT group compared with the delayed ADT group: in the immediate ADT group, only 3 of the 7 deaths were due to prostate cancer compared with 16 of the 18 cancer-specific deaths in the delayed ADT group (Messing et al., 1999). In the final analysis, with a median 11.9 years of follow-up, there was a significant improvement in overall survival (HR = 1.84, $P = 0.04$) and progression-free survival (HR = 4.09, $P = 0.004$) associated with immediate ADT (Messing et al., 2006). Based on this randomized, prospective trial, there appears to be a benefit to immediate ADT in those men with histologic evidence of lymph node metastases at the time of radical prostatectomy. However, in addition to being a relatively small study, there were limitations that limit its applicability in modern practice. The delayed arm initiated hormonal therapy at clinical progression. Twenty percent of patients on the trial had a detectable postoperative PSA and thus had biochemical evidence of disease persistence. This further dilutes the study's interpretability in the adjuvant, no evidence of disease population. Finally, this was largely a study of bulky nodal disease, with a median number of positive nodes of 2, with some patients having up to 20 affected nodes. It is not clear these data apply to the patient with low-volume positive nodes with an undetectable PSA, because 20% to 40% can be cured with surgery alone (Moschini et al., 2016; Touijer et al., 2014).

Results in Locally Advanced or Asymptomatic Metastatic Disease or Disease Not Suitable to Local Treatment

A trial of immediate versus delayed ADT in men with locally advanced or asymptomatic prostate cancer was conducted by the Medical Research Council (MRC) Prostate Cancer Working Party Investigators Group (The Medical

Research Council Prostate Cancer Working Party Investigators Group, 1997). A total of 934 men were included (500 M0, 261 M1, and 173 Mx), with 469 randomized to immediate ADT and 465 randomized to delayed ADT. The study initially reported an improvement in the progression from M0 to M1 disease, improvement in local complication and pain, as well as an improvement in overall and prostate cancer–specific survival to immediate ADT. With longer follow-up, although the cancer-specific mortality remained statistically improved with early ADT, the overall survival advantage was no longer significant ($P = 0.09$) (Kirk, 2004). In addition, men in the delayed ADT arm had significantly more symptoms related to disease progression. Based on these data, the benefits of immediate ADT would seem to support its use.

Immediate versus delayed ADT was studied in another group ($n = 985$) of men not suitable for local treatment (refused local treatment; had decreased life expectancy, advanced local tumor stage, and/or severe comorbidities) (Studer et al., 2006). Unlike the MRC study, immediate ADT resulted in a significant, albeit small, improvement in overall survival but no difference in prostate cancer–specific mortality or overall symptom-free survival. Interestingly and importantly, in the delayed ADT arm, 30% died without ever needing treatment.

Results in Biochemically Recurrent Prostate Cancer

With serum PSA, there is a biochemically recurrent disease state defined as a rising PSA without clinical or radiographic evidence of metastatic disease after curative-intent local therapy. The timing of initiation of ADT in this setting is not clear, with many clinicians using a combination of factors including clinical comorbidities, absolute PSA level, PSA doubling times, and patient-driven anxiety to guide initiation of ADT (Dale et al., 2009). There has been one reported randomized prospective trial of 293 patients (261 had rising PSA after definitive local therapy and 32 had locally advanced disease) to immediate or delayed androgen deprivation (Duchesne et al., 2016). Patients with the most aggressive disease, as indicated by PSA doubling time less than 3 months were excluded. Patients randomized to the delayed arm, were recommended to wait to start ADT for at least 2 years, unless metastatic disease, symptoms from disease, or PSA doubling time decrease to less than 6 months occurred. **Interestingly, there was an overall survival advantage to immediate ADT (HR = 0.55, $P = 0.047$) found in this study, suggesting early ADT may be of value for some patients with recurrent disease.**

Immediate Versus Delayed Androgen Deprivation Therapy: Integrating the Data

1. **There is no survival benefit to immediate ADT in low-risk, localized prostate cancer.** For overall survival, men treated in this fashion appear to do significantly worse than those spared ADT in this setting.
2. **In locally advanced or asymptomatic metastatic prostate cancer, immediate ADT results in significantly better prostate cancer–specific survival and risk of local complications and pain progression, but not better overall survival.**
3. **In node-positive disease without primary treatment, there may be an advantage to immediate ADT. In bulky node-positive disease with radical prostatectomy, there is a significant survival advantage favoring immediate ADT.**
4. **In node-positive disease after surgery and in biochemically-recurrent disease, immediate ADT is associated with an improvement overall survival.**

Intermittent Versus Continuous Androgen Deprivation Therapy

Given the clear side effects associated with hormonal therapy, along with the often protracted disease course, depending on clinical stage, there has been an effort to decrease the duration of hormonal therapy, when appropriate. In addition to consideration of delayed ADT, a strategy of intermittent androgen deprivation would also decrease exposure to ADT.

Intermittent ADT was studied in a group of men with a rising PSA after primary or salvage radiotherapy (Crook et al., 2012). Specifically, men were randomized to receive intermittent or continuous androgen deprivation with a primary end point of overall survival. Intermittent treatment was provided in 8-month cycles, with nontreatment periods based on PSA levels. At a median follow-up of 6.9 years, there were 268 deaths in the intermittent therapy group and 256 deaths in the continuous therapy group: median overall survival was 8.8 years in the intermittent group versus 9.1 years in the continuous group (see Table 161.3). **Based on a noninferiority trial design, intermittent therapy was not inferior to continuous therapy for overall survival**. Disease-specific death (prostate cancer and related treatments) was more common in the intermittent therapy arm compared with the continuous-therapy arm (120 vs. 94, respectively). Conversely, deaths unrelated to prostate cancer were more common in the continuous-therapy arm compared with the intermittent-therapy arm (162 vs. 148, respectively).

Attrition from intermittent androgen deprivation progressively increased over time as patients either developed castration-resistant prostate cancer or died of another cause. Attrition only occurred in 5% of men in the first interval, whereas 68% had stopped intermittent therapy by the third interval. On the other hand, duration of intermittent ADT progressively shortened over time: the median nontreatment interval between cycles was 20.1 months for the first treatment cycle, 13.2 months for the second cycle, 9.1 months for the third, and 4 to 5 months thereafter. A secondary end point, improved quality of life in the intermittent therapy arm, was associated with significantly better scores for hot flashes, desire for sexual activity, and urinary symptoms. For the functional domains of physical, role, and global health the intermittent therapy arm was slightly better, but the differences were not significant.

Noninferiority trials require fewer subjects than for an equivalence trial, making them easier to accrue and complete. It is important to recognize that noninferiority is not the same as equivalence; trial design is based on a definition of noninferiority if a prespecified upper margin of a hazard ratio is not exceeded. In this trial, the upper limit was 1.25, meaning up to 25% more men on the intermittent arm could die of any cause and intermittent treatment would still be considered noninferior. In this trial, the upper limit of the 95% CI was 1.22, which is below 1.25 and therefore met the prespecified definition; however, intermittent ADT at the upper bound could be as high as 22% worse.

Intermittent ADT was also studied in a group of men with newly diagnosed metastatic prostate cancer (Hussain et al., 2013). After a 7-month induction of ADT in all patients, men whose PSA level had declined to 4 ng/mL or lower (indicating androgen sensitivity) were randomized to receive intermittent or continuous androgen deprivation with coprimary end points of overall survival and quality of life at 3 months after randomization. At a median follow-up of 9.8 years, median overall survival was 5.8 years in the continuous arm and 5.1 years in the intermittent arm (HR for death with intermittent therapy, 1.10; 90% CI 0.99–q1.23) (see Table 161.3). In this study, the CI for survival exceeded the upper boundary for noninferiority (1.20), meaning it is not possible to conclude that intermittent therapy was noninferior to continuous therapy. Furthermore, because the lower limit of the CI (0.99) did not exclude 1.00, it is not possible to conclude that intermittent therapy was significantly inferior to continuous therapy. **A reasonable clinical interpretation of this study is that intermittent therapy in men with metastatic prostate cancer may be worse**. Quality-of-life scores were significantly better in the intermittent arm (less likely to report impotence, better mental health) at 3 months. At 9 and 15 months, the quality-of-life scores favored intermittent therapy, but the differences were not significant.

The treatment schedules for intermittent androgen deprivation vary slightly between the rising PSA after radiation therapy trial (Crook et al., 2012) and the metastatic disease trial (Hussain et al., 2013): both used an induction period of ADT (8 months and 7 months, respectively). If the PSA was less than 4 ng/mL, both trials stopped ADT (in the intermittent arms). Androgen deprivation was restarted if the PSA reached 10 or 20 ng/mL, respectively, or for clinical symptoms. In the metastatic disease trial, ADT could also be restarted when the PSA reached baseline. The development of castration-resistant prostate cancer required the patient be on ADT and demonstrate clinical progression or PSA increases monthly for 3 months. In both trials, castration-resistant prostate cancer was managed with continuous ADT. The treatment schedules provide some guidance in managing patients on intermittent ADT, but there is no consensus on the ideal schedule (Hussain et al., 2016). When interpreting these non-inferiority intermittent ADT trials, clinicians should remember the “devil is in the details,” and a careful discussion with the individual patient is necessary to weigh advantages and potential advantages (Hussain et al., 2016).

Emerging Androgen Receptor–Associated Biomarkers

At the hub of androgen pathway inhibition therapy for prostate cancer lies the AR nuclear hormone receptor (Scher and Sawyers, 2005). Hormonal therapies for prostate cancer are ultimately dependent on blocking the activity of the AR. It is thus not surprising molecular aberrations in the AR, including truncating splice variants, missense mutations, and genomic amplifications, are emerging as powerful predictive biomarkers for therapeutic efficacy.

Androgen Receptor Splice Variants

One of the most common molecular alterations within the AR emerges under the selective pressure of androgen deprivation and androgen pathway blockade are a series of AR splicing aberrations that result in truncated mRNA and AR proteins that lack the ligand-binding domain (Guo et al., 2009; Li et al., 2013). These truncated splice variants that lack the ligand-binding domain are believed to be active as transcription factors in a similar fashion to full-length AR but are constitutively active and independent of the presence of androgen ligand (Li et al., 2013). Furthermore, all of the current hormonal therapies for prostate cancer rely on an intact ligand-binding domain; medical/surgical castration and abiraterone are effective through depletion of androgen ligands, and AR antagonists (bicalutamide, enzalutamide, apalutamide) act at the ligand-binding domain of the AR and disrupt ligand binding or interaction of transcriptional coactivators. It is therefore not surprising prostate cancers expressing these AR splicing variants would be insensitive to androgen pathway–targeted therapies.

The most clinically validated AR alteration emerging as a negative predictive biomarker for potent hormonal therapies such as abiraterone and enzalutamide is the splice variant named AR-V7. AR-V7 is a common splice variant lacking a full ligand-binding domain and, in its place, has a small unique cryptic exon that can be detected with modern molecular biology techniques. In a landmark study of patients with castration-resistant prostate cancer (CRPC) who were to receive either abiraterone or enzalutamide, the presence of AR-V7 transcript within the blood (extracted from circulating tumor cells) was strongly associated with a lack of benefit from these therapies (Antonarakis et al., 2014)**. None of the AR-V7–positive patients achieved a PSA response with either abiraterone or enzalutamide, compared with a response rate of more than 50% for AR-V7–negative patients.** Furthermore, the hazard ratio associated with AR-V7–positive status for clinical or radiographic progression was 8.5 for enzalutamide and 16.5 for abiraterone treatment (both $P < 0.001$). The AR-V7 cryptic exon within the AR protein can also be detected by specific antibodies in addition to mRNA detection techniques. With use of an immunofluorescence assay detecting AR-V7 protein within circulating tumor cells in patient blood, AR-V7 positivity with this assay was also strongly associated with lack of benefit to potent AR signaling inhibitors (e.g., abiraterone/enzalutamide) (Scher et al., 2016). **Patients with AR-V7–positive CTC had a much shorter median radiographic progression free survival (2.3 vs. 14.5 months, $P < 0.001$), and importantly, on multivariate analysis, AR-V7 status was the strongest predictor of overall survival (HR = 4.15, $P < 0.001$). Interestingly, AR-V7–**

positive patients had a more favorable survival if treated with taxane chemotherapy compared with AR-targeted therapy (HR = 0.24, *P* = 0.035). Notably, the presence of AR-V7 in the CRPC setting increases with line of therapy from less than 5% incidence in the first line to more than 30% in the third or more line. This assay, which is now clinically available, can aid in therapeutic decision making in the refractory CRPC setting.

Androgen Receptor Gene Amplification and Mutation

In addition to ligand-binding domain deficient splice variants, there are other emerging AR-centric biomarkers to be considered in the context of potent hormonal therapies. A well-annotated adaptation mechanism for CRPC under the selection pressure of ligand deprivation is amplification or overexpression of the *AR* gene (Koivisto et al., 1997; Visakorpi et al., 1995). Modern molecular biology techniques can extract and analyze cell-free DNA (cfDNA) from the blood of patients with prostate cancer and allow for the interrogation of cancer-specific AR genomic events such as amplification (Kohli et al., 2018; Lallous et al., 2016; Wyatt et al., 2016). Similar to AR splice variants, ***AR* gene amplification has been strongly associated with poor outcomes for patient with metastatic CRPC including a significant decrease in the likelihood of PSA response (~10% versus ~50%), progression-free survival (HR ~3), and even overall survival (HR ~3-5)** (Conteduca et al., 2017; Kohli et al., 2018; Wyatt et al., 2016)**.** It is not yet known whether this association is independent of other prognostic indices, including AR-V7 status. It has been well recognized that ligand-binding domain (LBD) mutations can emerge in the context of AR blockade and can confer resistance to AR antagonists (e.g., bicalutamide, flutamide). Analyses of metastatic bone biopsies suggest the mutation rate in CRPC may be as high as 10% (Taplin et al., 2003a). Using cfDNA analysis from patients being treated with and progressing on second-generation potent abiraterone has revealed that AR LBD mutations that become sensitive to glucocorticoids can develop in more than 20% of patients (Carreira et al., 2014). Similar mutations have been detected upon resistance to other potent AR antagonists such as enzalutamide and apalutamide, and these AR mutations are associated with worse outcomes (Conteduca et al., 2017; Joseph et al., 2013; Lallous et al., 2016; Rathkopf et al., 2017). AR antagonists, such as darolutamide, have been developed that may overcome these AR LBD mutations (Moilanen et al., 2015). As the AR aberrations in the LBD (amplification, splice variants, mutations) are adaptive causes of resistance to potent AR-targeted therapies, current efforts are underway to develop novel therapeutics that either degrade or target other domains (N-terminal) of the AR (Liu et al., 2014; Moilanen et al., 2015).

Treatment of Castration-Resistant Prostate Cancer

Emmanuel S. Antonarakis MD, Michael A. Carducci MD

During the past several decades, endocrine manipulations developed to inhibit hormone-sensitive prostate cancer growth and differentiation have constituted the basic strategy for the systemic control of prostate cancer. Suppression of gonadal testosterone is the central principle of androgen deprivation therapy (ADT), and this represents one of the most effective systemic treatments known for solid tumors. Although the therapy is extremely effective initially, almost all patients eventually develop biochemical and clinical evidence of treatment resistance. The outcomes with conventional endocrine therapy have changed significantly but only modestly during the past few decades. Progression-free and overall survival figures of patients with metastatic disease with various methods of ADT have ranged from 12 to 20 months and 24 to 36 months, respectively (Crawford et al., 1989; Denis et al., 1993; Eisenberger et al., 1998; Leuprolide Study Group, 1984). Whereas somewhat longer survival times are reported in the more recent studies, this is most likely because of a “lead time” effect observed in contemporary populations of patients. The development of ADT resistance (i.e., cancer progression despite castrate levels of serum testosterone) is a universal state that affects all patients treated with ADT. Undoubtedly, further improvement in the outcome of patients with metastatic castration-resistant prostate cancer (mCRPC) rests on the use of nonhormonal approaches that can effectively control the growth of the disease. However, recent understandings of the biology of castration-resistant prostate cancer (CRPC) have also led to the development of next-generation androgen receptor (AR)–targeting therapies, and some of these have also led to substantial clinical benefits.

During recent years, clinical investigations testing nonhormonal approaches have shown that systemic chemotherapy improves survival and quality of life in patients with castration-resistant disease. Advances in the understanding of the biology of prostate cancer and the characterization of key molecular pathways have added an important new dimension for treatment and the opportunity to design disease-specific targeted treatment approaches. Evolving data suggest that targeted approaches may play an important role in the treatment of prostate cancer that may improve the outcome in patients.

Progress in cell and molecular biology during the past decade has also enhanced our understanding of the mechanisms involved in the progression of prostate cancer, and this may provide the opportunity for rational planning of the appropriate timing of systemic therapeutic intervention with the objective of preventing or delaying progression of disease to lethal proportions. Cancer cells demonstrating the castration-resistant phenotype can be identified during the early stages of development of prostate cancer. Somatic alterations of the AR are frequently observed in patients with evidence of disease progression after androgen deprivation. It has also been demonstrated that during cancer progression, in the absence of androgens, a molecularly altered AR can still undergo ligand-dependent activation by other hormones such as estrogens and progestational agents, as well as non–ligand-dependent activation by growth factors and cytokines (Feldman and Feldman, 2001; Gelmann, 2002; Nelson et al., 2003). The observation that the AR can still be activated even after long-term gonadal ablation suggests that it continues to play an important role in prostate cancer growth and may indeed be a reasonable target for treatment in patients with castration-resistant disease, as exemplified by success with abiraterone and enzalutamide.

In the presence of androgens, prostatic cancer growth is based on a cell proliferation rate that exceeds that of cell death (Isaacs et al., 1992). Androgen ablation primarily affects the cell death rate by inducing a swift apoptotic cascade. As the tumor progresses, the threshold of apoptosis progressively rises to a point at which cell proliferation exceeds cell death (Berges et al., 1995). This results in the accumulation of endocrine-independent cells that eventually dominate the biologic behavior of prostate cancer in late stages.

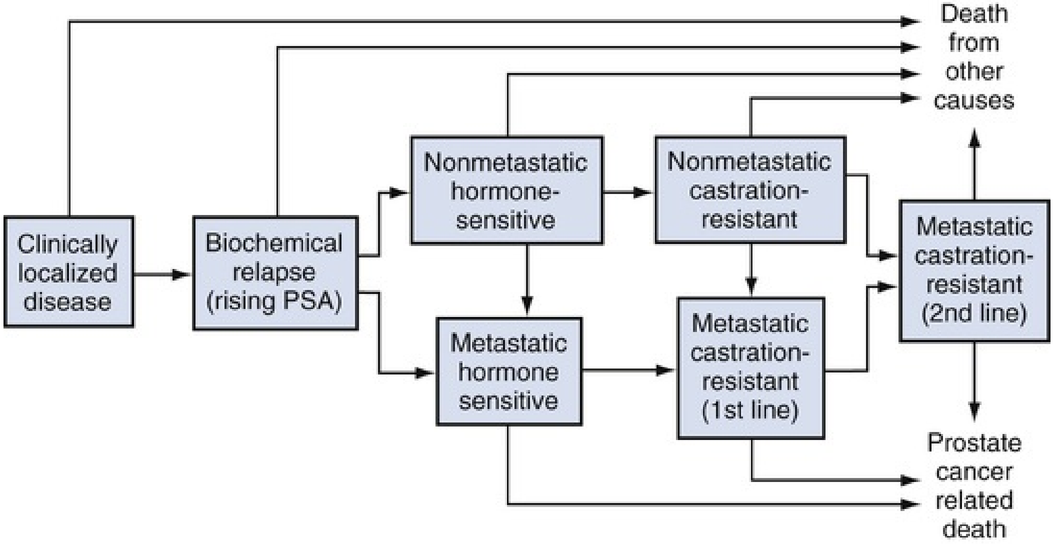
Preclinical data suggest that the relatively low growth fraction expressed by prostate cancer cells (compared with other common adenocarcinomas) may be a determining factor to explain the relative insensitivity to conventional cytotoxic chemotherapy. The proliferation rate of prostate cancer cells, which is directly proportional to the growth fraction, appears to increase with tumor progression especially after androgen ablation. Cell proliferation antigens, such as Ki-67 expressed by cycling cells, may have important prognostic and therapeutic implications, because most of the conventional cytotoxic chemotherapeutic agents available are usually more effective in tumors with high proliferative rates such as lymphomas, small cell lung carcinomas, and germ cell tumors.

Changes in differentiation pathways in prostate cancer have been increasingly emphasized, particularly in the form of neuroendocrine/anaplastic cells (diSant'Agnese, 1995). Evolving experience suggests that this aggressive clinical entity may be responsive to treatment regimens frequently used for comparable tumors at other sites with similar phenotypic characteristics, such as small cell carcinoma of the lung. There is strong evidence to support the relationship between prostate cancer growth and various peptide growth factors (Djakiew et al., 1991; Hofer et al., 1995; Kaplan et al., 1999; Nelson et al., 2003; Steiner, 1993). Peptide growth factors may also exert their effects through the activation of the AR. Androgens are capable of inducing stromal production of various growth factors that could replace the androgen requirements for cell growth and differentiation (Lee, 1996). In addition, cytokines released primarily by stromal cells, such as interleukin-6, may also be important in the pathogenesis of prostate cancer. Indeed, small molecule inhibitors and other modalities of treatment (e.g., monoclonal antibodies) are being actively designed to target intracellular pathways associated with the expression of various growth factors and their receptors. Such strategies have involved inhibition of receptor tyrosine kinase activity and other intracellular molecular pathways of signal transduction as well as other critical pathways of cell growth and survival.

Clinical Considerations

Disease Assessment and Prognostic Considerations

Conventional staging criteria, such as the tumor, node, metastases (TNM) staging system, do not describe the extent of disease beyond a simple anatomic classification, and they are not very helpful in the management of patients with recurrent or advanced prostate cancer. Treatment practices have resulted in the creation of different disease states as described by Scher et al. (2008). This system of “clinical states” allows classification of patients into a more relevant fashion and is increasingly being used throughout the literature. Fig. 162.1 illustrates the natural history of prostate cancer relative to treatment practices and identifies the various clinical states according to the response status to different therapies. Throughout this chapter, prognostic and therapeutic considerations are largely based on the concepts proposed by this classification model.



Death from other causes
Nonmetastatic hormone-sensitive
Nonmetastatic castration-resistant
Clinically localized disease
Biochemical relapse (rising PSA)
Metastatic castration-resistant (2nd line)
Metastatic hormone sensitive
Metastatic castration-resistant (1st line)
Prostate cancer related death

FIG. 162.1 Prostate cancer clinical states. *PSA,* Prostate-specific antigen. (Modified from Scher HI, Halabi S, Tannock I, et al.: Design and end points of clinical trials for patients with progressive prostate cancer and castrate levels of testosterone: recommendations of the Prostate Cancer Clinical Trials Working Group. *J Clin Oncol* 26:1148–1159, 2008.)

A complete disease evaluation is required to estimate the prognosis and to make therapeutic decisions. Critical baseline components should also be considered, including extent of disease, mode and site of progression (rising prostate-specific antigen [PSA] level alone, new bone metastasis, visceral and nodal metastasis), presence or absence of symptoms including bone pain, and response to previous endocrine treatment. Regular monitoring with serial bone scintigraphs and CT scans together with serum PSA levels provides important information in patients demonstrating evidence of disease progression while they are receiving hormone therapy. Usually the first manifestation of disease progression after hormone therapy is a rising serum PSA level. In patients with metastatic disease, a rise in serum PSA level precedes evidence of advancing disease on the bone scan, and during this time patients may remain relatively asymptomatic (Eisenberger et al., 1995). Routine evaluation of serum testosterone levels may provide important information for the choice of subsequent treatment. This is especially important when there may be reasons to suspect treatment noncompliance or if the choice of previous treatment involved regimens known not to result in a sustained suppression of serum testosterone to castrate levels (e.g., monotherapy with nonsteroidal antiandrogens, low-dose estrogens, or 5α-reductase inhibitors).

For several years, it was postulated that discontinuation of androgen suppression in patients who have not undergone orchiectomy may adversely influence the outcome of their disease in terms of progression and survival (Taylor et al., 1993). Similarly it has been shown that administration of exogenous testosterone and its derivatives may indeed produce a significant clinical flare, resulting in severe pain and neurologic, urologic, and coagulation complications in a small proportion of patients (Fowler and Whitmore, 1981; Manni et al., 1988). In a retrospective analysis of 205 patients with castration-resistant disease treated with chemotherapy, Hussain et al. (1994) evaluated various prognostic variables including orchiectomy. A multivariate analysis failed to indicate a significant correlation between previous orchiectomy and improved progression-free and overall survival. In these patients, all medical forms of androgen deprivation were discontinued at least 4 weeks before initiation of chemotherapy and, contrary to that suggested by Taylor et al. (1993), this did not significantly affect outcomes. Until this issue is resolved, the general consensus is to maintain all patients on luteinizing hormone–releasing hormone (LHRH) agonists or antagonists indefinitely, even during the course of subsequent therapies, including chemotherapy. Indeed almost all clinical trials that test novel therapies for men with castration-resistant prostate cancer (CRPC) mandate the continued suppression of serum testosterone levels, either with chronic ADT or with surgical castration.

Another important management aspect relates to antiandrogen withdrawal effects (Scher and Kelly, 1993; Small et al., 2004). Discontinuation of antiandrogens (steroidal and nonsteroidal) can result in short-term clinical responses expressed by decreases in PSA levels, symptomatic benefits, and (less frequently) objective improvements in soft-tissue and bone metastasis in a small proportion of patients. Because of this phenomenon, it has been recommended that in patients who appear to be progressing while on first-generation antiandrogens in combination with other forms of androgen deprivation (e.g., LHRH agonists), the first step should involve the carefully observed discontinuation of the antiandrogen, including serial monitoring of PSA levels for a period of 4 to 8 weeks before embarking on the next therapeutic maneuver.

The subsequent step is to determine which modality of treatment should be used next, either administration of second-line hormonal manipulation (including novel AR-directed therapies) or cytotoxic chemotherapy. There is an increasing body of data on second-line endocrine therapies, suggesting that there may be a role for this approach before institution of chemotherapy (Ang et al., 2009; Ryan, 2006; Small et al., 2004). Although initial response rates to the second-generation hormonal manipulations range between 20% and 60%, the median duration of such responses is short, ranging between 2 and 4 months. Agents that have been reported to produce some benefit in this setting include diethylstilbestrol (Smith et al., 1986), aminoglutethimide (Sartor and Myers, 1995), ketoconazole (Small et al., 2004), and corticosteroids (Storlie et al., 1995). Since around 2012, additional next-generation AR-targeting therapies have become available (e.g., abiraterone and enzalutamide) and have largely replaced the second-generation endocrine agents listed earlier. In view of the potential higher toxicity profile associated with cytotoxic chemotherapy, a sequential hormonal approach may be a reasonable alternative for those patients with relatively limited metastatic disease who remain asymptomatic at the time of disease progression (e.g., rising serum PSA value without other clinical manifestations or pain).

Another important consideration is the initial clinical assessment of the potential biologic behavior of these tumors when they become castration resistant. Evolving data evaluating the role of PSA dynamics suggest that the PSA doubling time (PSADT) predicts the rapidity of bone scan progression and survival (Armstrong et al., 2007; D'Amico et al., 2005; Robinson et al., 2008). Patients with PSADT shorter than 3 months have a particularly rapid clinical course and should possibly be considered for more aggressive management approaches. Similarly, patients with symptomatic bone pain or visceral-predominant disease may be better served with cytotoxic chemotherapy up front. In addition, poorly differentiated and neuroendocrine tumors usually have a low likelihood of significant and durable responses to further AR-directed therapies. The anaplastic/neuroendocrine phenotype is rare and requires special therapeutic considerations (see later). It has been suggested that systematic biopsies of disease sites in patients with clinically aggressive disease and relatively low serum PSA levels may demonstrate evidence of a neuroendocrine phenotype by immunostaining, which may be of prognostic and therapeutic significance. The usefulness of systematic biopsies in all patients with extensive metastasis and relatively low PSA levels, however, must be better defined before routine clinical application.

Nonmetastatic Castration-Resistant Prostate Cancer

The extraordinary stage migration that has affected all stages of prostate cancer has profoundly modified the spectrum of the clinical presentation of patients with castration-resistant disease. An increasing number of patients now begin ADT at very early stages of their disease course, often at the first sign of a rising PSA after local therapy, before clinical and radiologic evidence of metastasis is present. This group of patients, termed the M0 (nonmetastatic) castrate-resistant subset, is now seen in increasing proportions in the clinic. Given the changes in treatment practices with early initiation of androgen deprivation, it is conceivable that these numbers will continue to increase. At this time data on the natural history of these patients are evolving, but the strongest predictor of metastatic progression appears to be the PSA kinetics (PSA velocity, PSADT).

A number of clinical trials using second-line hormonal manipulations and noncytotoxic interventions (bone-targeted treatments) focusing on time to development of bone metastasis have provided some useful information. A report of 201 patients from a prospective clinical trial comparing the effects of the bisphosphonate zoledronate versus placebo in men with M0 castrate-resistant disease suggested that the time to radiographic metastasis may be very long. At 2 years, only 33% of these patients exhibited evidence of bone metastasis, with a median time to bone metastasis in this group of 30 months. The baseline PSA level (>10 ng/mL) and the PSA velocity independently predicted time to bone metastasis and survival (Smith et al., 2005). In a retrospective review of a similar group of patients who were prescribed ADT before the development of metastatic disease, the median time to clinical metastasis was 9 months. The pretreatment PSA level and the PSA nadir on ADT predicted metastasis-free survival (Dotan et al., 2005). The wide difference observed with these two reports (30 months vs. 9 months for time to bone scan metastasis) underscores the heterogeneity of this group of patients and the need for careful prospective evaluation. Their outcome is dependent on various factors, among which are pre-ADT characteristics (pretreatment PSA level, PSADT, initial stage, Gleason score), as well as differential response to hormonal treatment. However, it is probable that the risk of metastatic progression may be best estimated by PSA kinetics constructs such as PSADT and PSA velocity.

Until recently, there was no consensus regarding the most appropriate management for patients with nonmetastatic CRPC, although the sequential endocrine approach (using first-generation agents; e.g., bicalutamide, ketoconazole) was the most commonly used therapeutic modality. This all changed in February 2018, when the US Food and Drug Administration (FDA) approved the first drug specifically for use in men with nonmetastatic (M0) CRPC, apalutamide. This agent, which is a potent androgen receptor antagonist and is discussed in more detail later, was approved based on its ability to prolong metastasis-free survival compared with placebo in an M0 CRPC patient population (Smith et al., 2018). Apalutamide was the first drug for prostate cancer to receive regulatory approval based on the end point of metastasis-free survival (freedom from radiographic metastasis or death, whichever occurred first), opening the door for a new registrational end point. In July 2018 the FDA also approved enzalutamide (an AR antagonist that is also discussed later) for M0 CRPC based on a similar placebo-controlled trial demonstrating improved metastasis-free survival using this agent (Hussain et al., 2018). Unlike apalutamide that first entered the market in the M0 CRPC space, enzalutamide had previously received FDA approval for metastatic (M1) CRPC several years earlier.

Metastatic Castration-Resistant Prostate Cancer

Patients with mCRPC represent a heterogeneous population with respect to their clinical and disease characteristics at the time of disease progression on ADT. Metastatic prostate adenocarcinoma has an overwhelming predilection to involve the bone. Although the explanation for this unique metastatic pattern has not been completely elucidated, it may reflect the combination of various biologic factors (tumor-specific and host-specific) present at the time of metastatic spread. Circulating prostatic adenocarcinoma cells are arrested in the cortical and medullary bone spaces, where they subsequently adhere to bone surfaces through specific receptors for moieties such as integrins, collagens, laminin, and other bone-derived proteins. Cell growth is subsequently promoted by a number of factors such as hormones, growth factors, and stromal-epithelial interactions, most of which operate in the bone marrow. Expansion of tumor cells in the bone may cause pain, compression of spinal nerves or the spinal cord, or pathological fractures. In addition, extensive bone marrow replacement may cause impairment in hematologic function (most often manifested as myelophthisic anemia and thrombocytopenia).

Clinical involvement of visceral sites (excluding lymph nodes) is less common, even in patients with widespread castration-resistant disease. Even more rare is the occurrence of visceral disease in the absence of any bone involvement. Data from prospective clinical trials involving men with mCRPC suggest that radiographic evidence of visceral metastasis is observed in fewer than 20% of patients, whereas about 30% to 40% have demonstrable soft-tissue nodal disease. Because the majority of tumor burden in metastatic prostate cancer is found in bone, responses to treatment (e.g., tumor shrinkage) in soft-tissue sites alone (e.g., nodal or visceral sites) may not reflect a major treatment benefit because it represents only a small proportion of the overall disease burden. For this reason, the evaluation of “response rate” as the primary end point in clinical trials of mCRPC is discouraged, and “progression-free survival” (PFS) (that takes into account radiographic progression of bone and/or soft-tissue disease) is a much more acceptable trial end point (Scher et al., 2008).

Patients with mCRPC may experience a range of hematologic deficiencies caused primarily by the disease or by its treatment. Anemia is the most common hematologic abnormality, which can be explained by a variety of factors, such as anemia of chronic disease, bone marrow invasion, blood loss, and, rarely, secondary to a microangiopathic hemolytic anemia usually associated with a consumption coagulopathy (disseminated intravascular coagulation). A decrease in the red blood cell count of patients with advanced CRPC commonly results from a combination of factors, such as previous treatment with local irradiation of bone marrow (especially pelvic bones), systemic use of chemotherapy and radiopharmaceuticals, long-term androgen deprivation, as well as from extensive bone marrow invasion by a tumor resulting in substantial decrease in bone marrow reserves. The use of erythropoietin has been popular in the past. However, use of erythropoietin-stimulating agents has fallen out of favor and should be used with caution, because evidence is now mounting that these agents may increase mortality in cancer patients (Bennett et al., 2008). Thrombocytopenia (and, more rarely, leukopenia) is usually a complication of extensive radiation therapy or systemic chemotherapy. As an end-stage process, rapidly growing tumors with bone marrow involvement may result in pancytopenia. Thrombocytosis is also a nonspecific manifestation associated with many neoplastic conditions, including prostate cancer. However, clotting complications associated with thrombocytosis are rarely seen in men with prostate cancer, and treatment is not usually necessary.

Among the most important urologic sequelae of advanced prostate cancer is the development of obstructive uropathy. This complication, usually related to the primary disease or to pelvic/retroperitoneal adenopathy, can be devastating in terms of quality of life, and it may even present major therapeutic implications. In addition to an increased incidence of infection and pain, obstructed kidneys may critically impair renal function to a point at which some chemotherapeutic agents (which depend largely on renal mechanisms for their clearance) cannot be safely used. In general, patients who are otherwise considered candidates for treatment with cytotoxic drugs are best managed by first relieving the obstruction either with placement of internal ureteral stents or by percutaneous nephrostomy tubes.

Finally, one of the greatest emergencies in oncology is the development of spinal cord compression (Sorensen et al., 1990). Because of the frequent involvement of vertebral bodies by metastatic prostate cancer, the incidence of cord compression is of particular concern and requires expeditious management to preserve or reverse neurologic function (see later).

Key Points: Clinical Considerations

- Evaluate the extent and aggressiveness of the disease before contemplating therapy.
- Realize that the critical determinants are presence or absence of

radiographic metastases, biochemical versus clinical progression, and presence or absence of symptoms (e.g., pain).

- Understand that the presentation of metastatic CRPC is heterogeneous in terms of distribution of metastatic sites and disease kinetics.
- Consider the use of apalutamide or enzalutamide in men with nonmetastatic (M0) CRPC, which are FDA approved for this indication, to delay the onset of radiographic metastases.

Cytotoxic Chemotherapy

Evaluation of Treatment Efficacy

Measurement of therapeutic efficacy in the clinical trial setting for patients with advanced prostate cancer may be confounded by significant methodologic challenges. The most common metastatic site in these patients is bone, manifested by diffuse osteoblastic lesions that cannot be measured reliably by current methods (termed “nonmeasurable” disease). Soft-tissue or visceral metastatic sites that allow serial measurements (“measurable” disease) are uncommon and represent only a small fraction of the total metastatic burden of the disease. Selection of bidimensionally measurable disease sites to assess therapeutic efficacy with serial tumor measurements has been the subject of significant criticism, because many patients may only harbor metastases in osseous sites. Furthermore, patients with soft-tissue metastasis (especially visceral metastases) are often considered a subgroup with biologic and clinical features distinct from those with bone-only metastases. As a result of these potential caveats, the evaluation of “response rate” as the primary end point in clinical trials of mCRPC has been discouraged, and the use of PFS (taking into account radiographic progression of bone and/or soft-tissue disease) has become a much more acceptable trial end point in instances in which overall survival is not a feasible end point (Scher et al., 2008).

A number of prognostic models evaluating baseline and post-treatment characteristics have been developed to help dissect the heterogeneity of CRPC in the context of various cytotoxic and noncytotoxic therapies (Armstrong et al., 2007; Halabi et al., 2003, 2013b; Smaletz et al., 2002). Among numerous clinical and laboratory parameters with consistent prognostic significance across a range of therapeutic settings are the patient's functional status (performance status), presence of pain, baseline hemoglobin level, baseline PSA level, baseline alkaline phosphatase, baseline LDH level, extent of bone involvement (number of lesions or pattern/distribution of bone lesions), and presence of visceral disease. Quantitative methods to evaluate circulating tumor cell (CTC) numbers and various PSA constructs (e.g., >30% PSA reduction) are among the post-treatment parameters with the strongest prognostic significance (Armstrong et al., 2007; de Bono et al., 2008; Halabi et al., 2013a; Scher et al., 2004).

Preclinical observations have suggested that some drugs may reduce PSA secretion without affecting tumor growth, whereas other drugs may affect tumor growth without necessarily reducing PSA levels (Eisenberger and Nelson, 1996; Larocca et al., 1991; Seckin et al., 1996). Although these laboratory observations are likely to be clinically relevant, assays used to evaluate a separate drug effect on PSA secretion still require careful validation. A PSA consensus meeting developed by several leading investigators in the field generated initial guidelines with regard to the use of the PSA test for clinical trials in patients with CRPC (Bubley et al., 1999). These guidelines were updated and now also provide a consensus on the use of radiologic end points as well as clinical end points (e.g., pain) for the evaluation of men with advanced CRPC (Scher et al., 2008). Undoubtedly, new biomarkers are needed to enhance our ability to identify rapidly the active treatments for CRPC, and one such marker may be the enumeration of CTCs (at baseline and after a period of treatment) (de Bono et al., 2008). Furthermore, evolving noncytotoxic and targeted therapies may require a new set of end points and identification of drug-specific intermediate biomarkers that reflect mechanism-specific biologic activity.

Chemotherapeutic Agents

Most of the chemotherapeutic agents available in oncologic practice have been used in patients with CRPC, either as single agents or in various combinations. Historical examples have included cyclophosphamide, 5-fluorouracil, estramustine, vinorelbine, etoposide, cisplatin, carboplatin, doxorubicin, mitoxantrone, paclitaxel, and docetaxel (Eisenberger, 1988). With the exception of docetaxel (and the related agent, cabazitaxel) and perhaps mitoxantrone, most other cytotoxic agents are no longer being used with frequency because they have not been associated with either symptomatic improvements or extension of survival. Evolving data with selected chemotherapy agents during the new millennium suggest that the survival of patients with advanced CRPC receiving first-line chemotherapy is now somewhere between 16 and 20 months (Petrylak et al., 2004; Tannock et al., 2004) as opposed to 6 to 12 months as previously described with historical agents (Eisenberger, 1988).

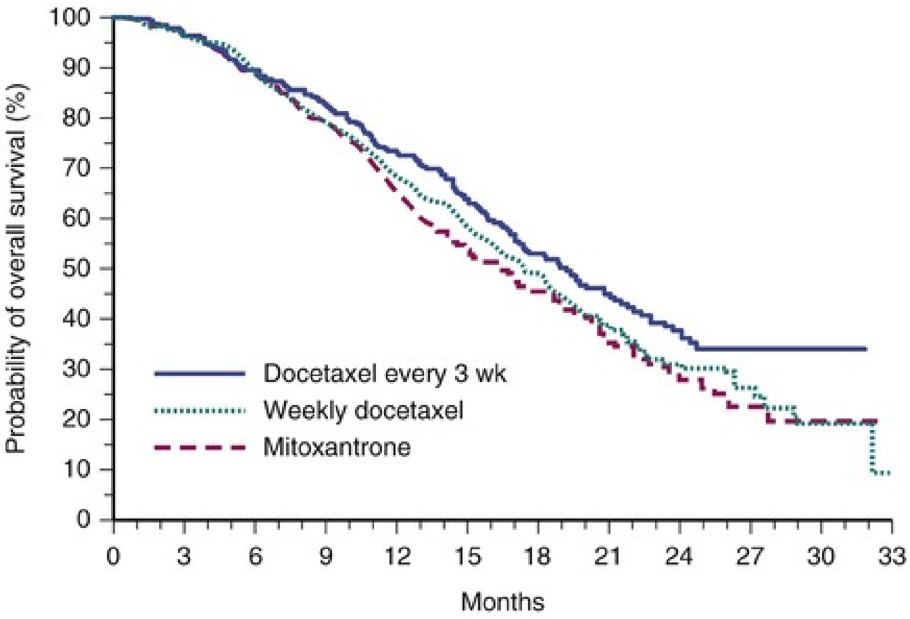
Mitoxantrone

A first step forward in the chemotherapeutic management of CRPC came with mitoxantrone. This agent, a semisynthetic anthracycline, had previously shown modest symptomatic benefits but with minimal evidence of objective antitumor activity (Osborne et al., 1983; Rearden et al., 1995). In addition, mitoxantrone appeared to have its maximal palliative effect in combination with low-dose corticosteroids (Moore et al., 1994). In two seminal prospective randomized trials of mitoxantrone plus prednisone versus prednisone alone (Tannock et al., 1996) or mitoxantrone plus hydrocortisone versus hydrocortisone alone (Kantoff et al., 1999), the combination resulted in significant improvements of various quality-of-life parameters, including pain, but survival was not significantly improved in either trial. These studies provided the justification for the FDA to approve mitoxantrone with prednisone in 1997 for patients with *symptomatic* CRPC. Even though the use of first-line mitoxantrone has dramatically declined with the advent of more effective chemotherapy agents (docetaxel and cabazitaxel; see later), mitoxantrone is still sometimes useful for patients with docetaxel- and cabazitaxel-refractory disease, or in those with a marginal performance status in which the more toxic taxane agents may not be well tolerated.

Docetaxel

The next significant advance in the use of chemotherapy for metastatic CRPC came with docetaxel, a member of the taxane family. This agent acts by inducing apoptosis in cancer cells through TP53-independent mechanisms that are thought to be a result of the inhibition of microtubule depolymerization and the blockade of antiapoptotic signaling. The induction of microtubule stabilization intracellularly through β-tubulin interactions causes guanosine triphosphate-independent polymerization and cell cycle arrest at the G_2M phase. In addition, docetaxel has been found to induce BCL2 phosphorylation in vitro, a process that has been correlated with caspase-3 activation and loss of its normal antiapoptotic activity. Unable to inhibit the proapoptotic molecule BAX, phosphorylated BCL2 may also induce apoptosis through this alternate pathway. However, additional mechanisms may also be important, such as CDKN1B (p27) induction and repression of BCL-XL. Finally, it has emerged that docetaxel may exert part of its therapeutic effect by impairing association of the cytosolic AR to microtubules, thereby disrupting the transport of the ligand-bound AR from the cytoplasm into the nucleus on board the microtubules (Darshan et al., 2011; Zhu et al., 2010).

Early data with docetaxel monotherapy initially suggested that this compound may have significant activity in prostate cancer even as a single agent (Beer, 2004; Friedland et al., 1999; Picus and Schultz, 1999). In 2004 docetaxel became the chemotherapy drug of choice for the treatment of mCRPC based on a large phase III randomized trial, termed TAX 327 (Fig. 162.2), which demonstrated superiority beyond the previous standard: mitoxantrone plus prednisone (Tannock et al., 2004). The TAX 327 study enrolled 1006 patients with no previous chemotherapy treatment and with stable pain scores into one of three study arms (all with concomitant prednisone 5 mg twice daily): mitoxantrone 12 mg/m^2 intravenously every 21 days; docetaxel 75 mg/m^2 intravenously every 21 days; or docetaxel 30 mg/m^2 intravenously every 7 days. Patients remained on androgen suppression (e.g., LHRH agonists or orchiectomy), but all other second-line hormonal agents were discontinued. The anticipated treatment duration was 30 weeks (i.e., 10 cycles of therapy) in all study arms, although more patients completed treatment in the every-3-week docetaxel group than in the mitoxantrone group because of differences in disease progression rates (46% vs. 25%). After a median follow-up of 20.7 months, overall survival in the every-3-week docetaxel group was 18.9 months (with a pain response rate of 35% and a PSA response of 45%), compared with weekly docetaxel at 17.3 months (and 31% and 48%), respectively. This translated into a 24% relative reduction in the risk of death (95% confidence interval [CI] 6% to 48%, P = 0.0005) using every-3-week docetaxel (see Fig. 162.2). Meanwhile, patients on the mitoxantrone arm experienced a median survival of 16.4 months, a pain response of 22%, and a PSA response of 32%. The conclusion of the TAX 327 trial was that every-3-week docetaxel was superior to weekly docetaxel and every-3-week mitoxantrone. This was a landmark study, because it showed for the first time that chemotherapy could improve survival in mCRPC patients.



No. at risk						
Docetaxel every 3 wk	335	296	217	104	37	5
Weekly docetaxel	334	297	200	105	29	4
Mitoxantrone	337	297	192	95	29	3

FIG. 162.2 Overall survival in the TAX 327 study. (Data from Tannock I, DeWit R, Berry W, et al.: Docetaxel plus prednisone or mitoxantrone plus prednisone for advanced prostate cancer. *N Engl J Med* 351:1502–1512, 2004.)

Toxicity in the every-3-week versus weekly docetaxel groups was notable because of an increase in hematologic events in the every-3-week group (3% neutropenic fever vs. 0; 32% grade 3/4 neutropenia vs. 1.5%) but slightly lower rates of nausea and vomiting, fatigue, nail changes, hyperlacrimation, and diarrhea. Neuropathy was slightly more common in the every-3-week group (grade 3/4 neuropathy in 1.8% vs. 0.9% in the weekly group). Quality-of-life responses as measured by the FACT-P instrument did not differ significantly between the two docetaxel schedules but were more favorable than in the mitoxantrone group.

The Southwest Oncology Group (SWOG) 9916 study was the second large phase III trial (Fig. 162.3) to evaluate docetaxel (Petrylak et al., 2004). In this study, 770 patients with progressive CRPC were randomly assigned to oral estramustine (280 mg three times daily) plus docetaxel (60 mg/m^2 IV every 21 days) versus mitoxantrone (12 mg/m^2 IV every 21 days) plus prednisone. Median overall survival in the SWOG 9916 study was longer in the docetaxel-estramustine group than in the mitoxantrone-prednisone group (17.5 vs. 15.6 months, $P = 0.02$), with a corresponding hazard ratio (HR) for death of 0.80

(95% CI 0.67–0.97) (see Fig. 162.3). Because of the high rate of thromboembolic events with estramustine, prophylactic low-dose warfarin and aspirin were added to that study arm. Similarly, 20% and 15%, respectively, of patients in the docetaxel-estramustine arm had grade 3/4 gastrointestinal and cardiovascular toxicities. Although comparisons between the docetaxel arms across these two seminal trials may not be appropriate because of differences in schedule, patient populations, and docetaxel dosing (60 mg/m^2 in SWOG 9916 and 75 mg/m^2 in TAX 327), it was concluded that estramustine is unlikely to add significantly to the activity of single-agent docetaxel. For this reason, and because of its thromboembolic toxicities, estramustine is currently only a historic remnant and is no longer generally used in the United States.

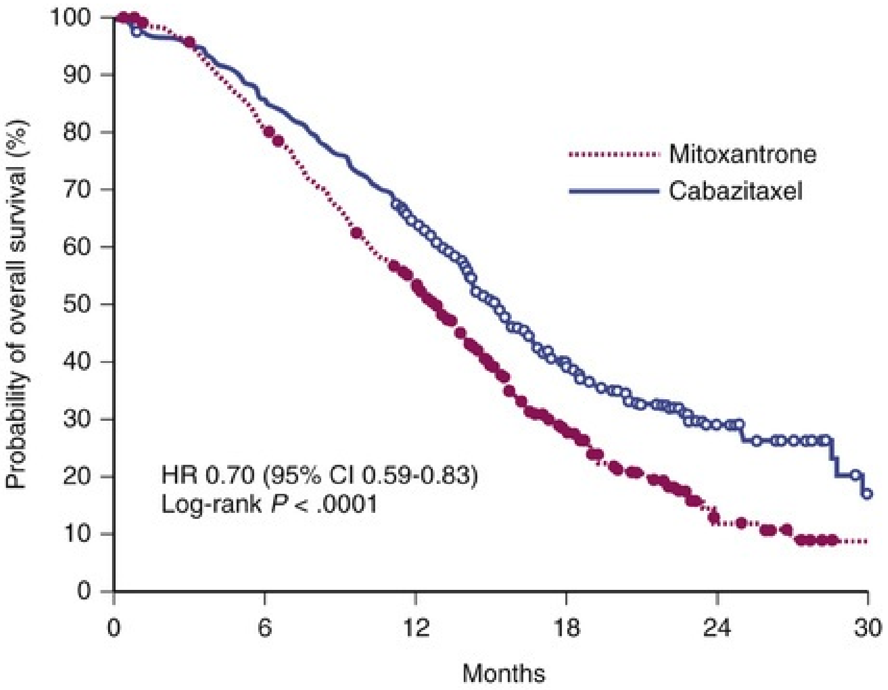
A number of experimental agents have been investigated in combination with docetaxel in an attempt to improve on the efficacy of single-agent docetaxel. However, the results of most phase III trials of docetaxel-based combination therapy have been disappointing. Although serum vascular endothelial growth factor (VEGF) levels correlate inversely with survival, antiangiogenic agents (bevacizumab, aflibercept, and lenalidomide) combined with docetaxel have not improved overall survival. Combinations of bone-targeted agents such as atrasentan, zibotentan, and dasatinib with docetaxel have also produced disappointing results. Finally, high-dose vitamin D (calcitriol) combined with weekly docetaxel also demonstrated no survival advantage beyond docetaxel alone. Potential reasons for the failure of docetaxel-based combination therapies include marginal activity of the agents that were combined with docetaxel, lack of well-conducted randomized phase II trials before initiating phase III studies, as well as dose reductions of docetaxel that were often required as a result of overlapping drug toxicities (Antonarakis and Eisenberger, 2013).

Cabazitaxel

Until 2010 effective life-prolonging therapies for men with docetaxel-refractory prostate cancer were lacking. This changed with the advent of cabazitaxel, a second-generation taxane agent that was FDA approved in 2010 for the treatment of docetaxel-pretreated mCRPC based on the results of a pivotal randomized phase III (TROPIC) trial (Fig. 162.4). Cabazitaxel is a novel tubulin-binding taxane that differs from docetaxel and paclitaxel because of its poor affinity for P-glycoprotein, the adenosine triphosphate–dependent drug efflux pump (Paller and Antonarakis, 2011). In preclinical studies using cancer cell lines and mouse xenograft models, cabazitaxel was shown to be active in docetaxel-sensitive tumors as well as in those with primary or acquired docetaxel resistance (Attard et al., 2006). The first hint of cabazitaxel's safety and efficacy in men with prostate cancer came during phase I testing, in which cabazitaxel was administered by intravenous infusion every 3 weeks at escalating doses of 10 to 25 mg/m^2 (Mita et al., 2009). In that study, the principal dose-limiting toxicity (DLT) was neutropenia. Given the lack of cross-resistance between this agent and docetaxel, and based on early reports of favorable responses in men with CRPC from this phase I trial, a phase III trial was launched to evaluate its activity.



Number at risk						
Mitoxantrone	377	300	188	67	11	1
Cabazitaxel	378	321	231	90	28	4

FIG. 162.4 Overall survival in the TROPIC study. *CI,* Confidence interval; *HR,* hazard ratio. (From de Bono JS, Oudard S, Ozguroglu M, et al.: Prednisone plus cabazitaxel or mitoxantrone for metastatic castration-resistant prostate cancer progressing after docetaxel treatment: a randomised open-label trial. *Lancet* 376:1147–1154, 2010.)

The safety and efficacy of cabazitaxel in patients with advanced prostate cancer were definitively evaluated in the TROPIC trial conducted in 146 institutions across 26 countries, which recruited 755 men with mCRPC who had progressed after docetaxel-based chemotherapy (de Bono et al., 2010). Of these, 377 patients were randomized to receive mitoxantrone 12 mg/m^2 intravenously every 3 weeks (with oral prednisone 10 mg daily), and 378 patients were assigned to receive cabazitaxel 25 mg/m^2 intravenously every 3 weeks (plus prednisone). After a median follow-up of 12.8 months, overall survival in men receiving cabazitaxel was 15.1 months compared with 12.7 months in men receiving mitoxantrone (HR 0.70, $P < 0.0001$) (see Fig. 162.4) (de Bono et al., 2010). Compared with mitoxantrone, cabazitaxel also significantly lengthened PFS (2.8 months vs. 1.4 months, $P < 0.0001$), extended time to PSA progression (6.4 months vs. 3.1 months, $P = 0.001$), increased radiographic tumor response rates (14.4% vs. 4.4%, $P = 0.0005$), and increased PSA response rates (39.2% vs. 17.8%, $P = 0.0002$). There were no differences between the two treatment arms with respect to pain responses or time to pain progression. The results of this study formed the basis for the FDA's approval of cabazitaxel plus prednisone in June 2010 for the second-line treatment of docetaxel-refractory mCRPC.

In subset analyses, the survival advantage of cabazitaxel persisted regardless of whether patients experienced measurable disease or pain, or whether progression had occurred while receiving docetaxel or after a treatment holiday. In addition, cabazitaxel's survival benefit was most pronounced for men with Eastern Cooperative Oncology Group (ECOG) performance status 0 to 1 (vs. 2), and for patients with disease progression within less than 3 months of docetaxel initiation (vs. ≥3 months of docetaxel initiation) (de Bono et al., 2010). The last observation implies that cabazitaxel may be effective even in men with truly docetaxel-refractory disease, providing clinical evidence that there may not be significant cross-resistance between docetaxel and cabazitaxel.

The most common serious adverse events related to cabazitaxel were hematologic, including grade 3 to 4 neutropenia in 82% of patients (febrile neutropenia in 8%). Patients older than 65 years experienced a 6.6% higher rate of grade 3 neutropenia than younger patients. This degree of myelosuppression begs the question of whether a lower dose of cabazitaxel (e.g., 20 mg/m^2) may have been more appropriate; a randomized phase III trial (PROSELICA) comparing the safety and efficacy of these two doses of cabazitaxel (25 mg/m^2 vs. 20 mg/m^2 every 3 weeks) has answered this question (Eisenberger et al., 2017). That study, which was designed as a noninferiority trial in the post-docetaxel population, demonstrated that overall survival was no worse in the 20 mg/m^2 compared with the 25 mg/m^2 dose group (upper 95% confidence limit was 1.18, with the noninferiority margin set at <1.21), whereas grade 3 or 4 adverse events were less frequent at the lower cabazitaxel dose (40% vs. 55%, respectively). Based on the PROSELICA trial, the FDA modified the package insert in September 2017 to recommend a dose of 20 mg/m^2 in most mCRPC patients, although the 25 mg/m^2 dose is still a reasonable choice in select patients who are at lower risk of neutropenia. The option to use either dose of cabazitaxel is reflected in several national guidelines (Mohler et al., 2016). Other nonhematologic toxicities of cabazitaxel include grade 3 to 4 diarrhea (6%) and grade 3 to 4 fatigue (5%). Diarrhea is more common in patients older than 65 as well as in those with a history of previous radiation therapy. Encouragingly, although peripheral neuropathy (all grades) is observed in 14% of patients receiving cabazitaxel, only 1% of men develop grade 3 neuropathy (de Bono et

al., 2010).

Given the favorable activity of cabazitaxel in docetaxel-pretreated patients, it was logical to evaluate cabazitaxel as first-line chemotherapy in men with mCRPC. To this end, an international randomized phase III trial (FIRSTANA) of docetaxel versus cabazitaxel (20 mg or 25 mg/m^2) in chemotherapy-untreated patients was recently reported (Oudard et al., 2017). Unfortunately, that trial failed to show superior overall survival of either dose-level of cabazitaxel compared with standard docetaxel in the chemotherapy-naive mCRPC setting, even though objective tumor response rates were numerically higher using cabazitaxel 25 mg/m^2 compared with docetaxel 75 mg/m^2. At the current time, therefore, cabazitaxel is not recommended or FDA approved for use as a first-line chemotherapy agent in mCRPC.

Platinum Agents

Although platinum-containing drugs (e.g., cisplatin, carboplatin) are generally not widely used (nor FDA approved) in unselected patients with mCRPC, there may be certain populations that benefit preferentially from these compounds. One such group are the patients with small cell neuroendocrine prostate cancer (discussed further, later), also sometimes called aggressive-variant prostate cancers. A limited number of clinical trials have shown that such patients with small cell or aggressive-variant prostate cancer may respond favorably, albeit for a short duration, to combination regimens consisting of cisplatin-etoposide or docetaxel-carboplatin (Aparicio et al., 2013). Recent molecular data have revealed that these small cell neuroendocrine prostate cancers are characterized by at least 2 out of 3 of the following parameters: *PTEN* loss, *TP53* mutation, and *RB1* loss (Aparicio et al., 2016). To this end, a recent randomized phase II trial comparing cabazitaxel versus cabazitaxel-carboplatin confirmed this molecular signature and showed longer PFS with the combination regimen in aggressive-variant mCRPC but not in usual-type mCRPC, potentially suggesting that aggressive-variant prostate cancer is a platinum-sensitive tumor (Aparicio et al., 2017). Finally, emerging data suggest that another potential platinum-sensitive mCRPC population may be those patients harboring DNA repair deficiency mutations. One example pertains to patients with germline *BRCA2* mutations, who appear to respond better to docetaxel-carboplatin than to docetaxel alone (Pomerantz et al., 2017). The full spectrum of platinum-sensitivity in mCRPC is an active area of investigation and has yet to be fully defined.

Key Points: Cytotoxic Chemotherapy

- Docetaxel is the standard first-line chemotherapy for mCRPC. It prolongs progression-free and overall survival, ameliorates pain, and improves quality of life.
- Toxicity of docetaxel includes myelosuppression, fatigue, peripheral edema, neurotoxicity, hyperlacrimation, and nail dystrophy.
- Cabazitaxel is as a second-line chemotherapy option for patients with mCRPC who have had progressive disease during or after docetaxel treatment. Both doses (20 mg/m^2 or 25 mg/m^2 every 3 weeks) are acceptable, and the lower dose has less toxicity.
- Side effects with cabazitaxel include neutropenia (including febrile neutropenia) and diarrhea but generally not neuropathy.
- Although it does not prolong survival, mitoxantrone has been approved to palliate symptoms associated with metastatic disease. It is sometimes used in patients who have previously received docetaxel and/or cabazitaxel or in those who would not tolerate these agents.
- Platinum agents are indicated in patients with small cell prostate cancer and perhaps in other subsets of mCRPC patients (e.g., those with combined *TP53* and *PTEN* inactivation or DNA repair deficiency mutations).

Next-Generation Hormonal Therapies

CYP17 Inhibition: Abiraterone and Other Agents

It has been recognized that the AR and ligand-dependent AR signaling commonly remain active and upregulated in men with castrate levels of testosterone (i.e., <50 ng/dL) (Debes and Tindall, 2004). Standard hormonal therapies such as LHRH agonists/antagonists inhibit gonadal androgenesis but do not affect androgen synthesis from adrenal or other extragonadal sources that may account for up to 10% of total androgen production. It has also been suggested that CRPC may produce intratumoral androgens autonomously (Mostaghel et al., 2007). In addition, overexpression of CYP17 has been demonstrated in tumors of men with CRPC (Stigliano et al., 2007). All of this laboratory evidence suggests that CRPC is not androgen independent and often remains hormone driven, implying that further suppression of nongonadal androgen sources may yield therapeutic gains.

Abiraterone acetate is an oral selective inhibitor of cytochrome P450 isoform 17 (CYP17), an enzyme that has 17,20-lyase and 17α-hydroxylase activity, and is a key regulator of extragonadal androgen synthesis. Phase I/II studies using abiraterone in men with CRPC (before and after docetaxel) showed a substantial number of PSA responses (PSA declines ≥50%) and also some partial radiologic responses in men with bony and soft-tissue metastases (Attard et al., 2008; Danila et al., 2010). Furthermore, abiraterone retains its activity even in patients with previous ketoconazole treatment (a weak CYP17 inhibitor) (Ryan et al., 2010). Common side effects of abiraterone include hypokalemia, hypertension, and pedal edema. These effects are explained by a syndrome of secondary mineralocorticoid excess, which improves with use of the mineralocorticoid receptor antagonist eplerenone or with the addition of prednisone, which blunts the ACTH drive. Importantly, patients receiving abiraterone must also continue treatment with an LHRH agonist/antagonist, whereas the clinical activity of single-agent abiraterone is largely unknown.

To evaluate conclusively the efficacy and safety of abiraterone in men with CRPC, a pivotal multicenter placebo-controlled blinded randomized phase III trial (COU-AA-301) was conducted in men with docetaxel-pretreated ketoconazole-naive mCRPC (de Bono et al., 2011). This trial randomized men (2

: 1) to receive either abiraterone 1000 mg daily plus prednisone 10 mg daily (*n* = 797) or placebo plus prednisone (*n* = 398). The trial met its primary end point, demonstrating a median overall survival of 14.8 months in the abiraterone arm and 10.9 months in the placebo arm (HR 0.65, $P < 0.0001$) (Fig. 162.5). In addition, when compared with placebo, abiraterone prolonged radiographic PFS (5.6 vs. 3.6 months, $P < 0.0001$), improved time to PSA progression (10.2 vs. 6.6 months, $P < 0.0001$), and produced more PSA responses (38% vs. 10%, $P < 0.0001$). Further analysis showed that abiraterone had significant benefits compared with placebo in terms of pain relief, patient-reported fatigue, delaying pain progression, and prevention of skeletal-related events (Fizazi et al., 2012; Logothetis et al., 2012). Based on the results of the COU-AA-301 study, the FDA approved abiraterone plus prednisone in April 2010 for the treatment of patients with mCRPC who have received previous docetaxel chemotherapy. The recommended dose of abiraterone is 1000 mg daily by mouth.

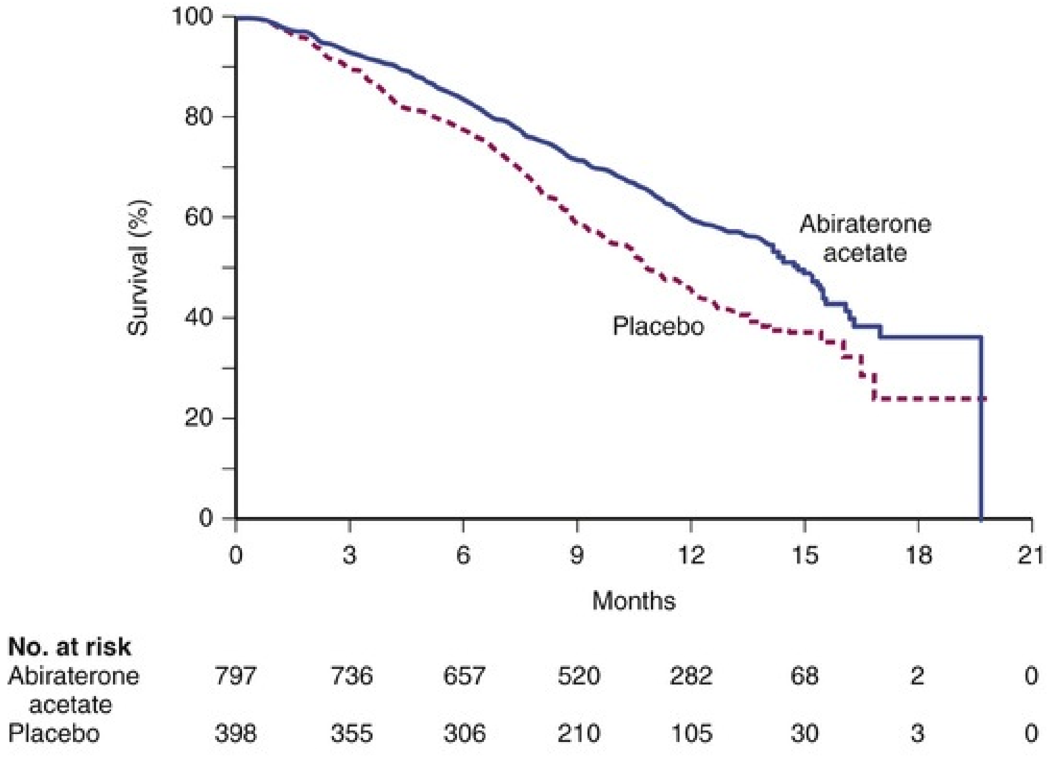


FIG. 162.5 Overall survival in the COU-AA-301 study. (Data from de Bono JS, Logothetis CJ, Molina A, et al.: Improved survival from metastatic prostate cancer with abiraterone acetate. *N Engl J Med* 364:1995–2005, 2011.)

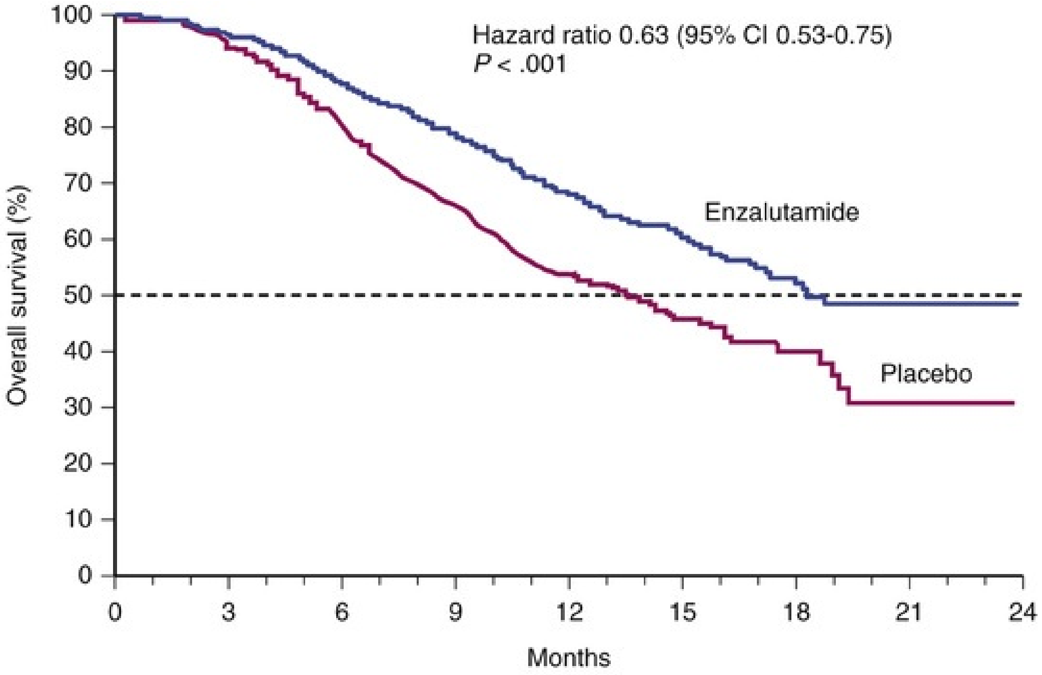
Because of the success of abiraterone in the post-docetaxel setting, a second randomized phase III trial (COU-AA-302) targeting men with docetaxel-naive CRPC was undertaken. This double-blind placebo-controlled study recruited asymptomatic or mildly symptomatic chemotherapy-naive patients with mCRPC and randomized them (1 : 1) to receive abiraterone (1000 mg) and prednisone (10 mg daily) or placebo and prednisone. The coprimary end points of this trial were radiographic PFS and overall survival. The study demonstrated a statistically significant difference in PFS in favor of the abiraterone arm (HR 0.43, 95% CI 0.35–0.52, $P < 0.0001$), representing a 57% reduction in the risk of radiographic progression with abiraterone (Ryan et al., 2013). The study also showed a strong trend toward improved overall survival and significantly delayed initiation of cytotoxic chemotherapy (26.5 months vs. 16.8 months). Importantly, in the final analysis, overall survival was significantly improved in the abiraterone arm (HR 0.81, 95% CI 0.70– 0.93, $P = 0.003$), reflecting a 19% reduction in the risk of death and meeting the prespecified significance level set by the O'Brien-Fleming rule (that required a P value of < 0.038) (Ryan et al., 2015). Once again, abiraterone produced additional benefits in the predocetaxel setting, including improved patient-reported quality-of-life outcomes (Basch et al., 2013). Based on the results of the COU-AA-302 trial, the FDA expanded the label for abiraterone to encompass all patients with mCRPC (i.e., including those who have not received docetaxel chemotherapy). Abiraterone is not currently approved for patients with nonmetastatic (M0) CRPC, a setting in which enzalutamide and apalutamide are approved.

Other agents that target the androgen signaling pathway through CYP17 inhibition are also in clinical development but have had less success thus far. Orteronel (TAK-700) has a similar mechanism of action to abiraterone; it is a nonsteroidal CYP17 inhibitor with potentially greater 17,20 lyase selectivity (i.e., impairing androgen synthesis preferentially over corticosteroid synthesis). Orteronel has been evaluated in two large placebo-controlled phase III trials (with prednisone in both arms) in men with mCRPC who were either chemotherapy naive or docetaxel pretreated. In the international ELM-PC5 (post-docetaxel) trial, although orteronel produced a significant improvement in PFS (HR 0.76, 95% CI 0.65–0.89, $P = 0.0004$), the study did not meet its primary survival end point (HR for survival: 0.89, 95% CI 0.74–1.06, $P = 0.19$) (Dreicer et al., 2014) and orteronel did not gain FDA approval. Interestingly, in countries where abiraterone was not available post-progression, survival was significantly improved with orteronel; whereas in countries where abiraterone was already approved; survival was not affected probably because of subsequent treatment with abiraterone. The phase III pre-chemotherapy (ELM-PC4) study had a similar fate. This study, which was a randomized trial of orteronel/prednisone versus placebo/prednisone in chemotherapy-untreated mCRPC patients, also failed to demonstrate an improvement in overall survival (HR 0.92, 95% CI 0.79–1.08; $P = 0.31$) (Saad et al., 2015). Therefore, although orteronel is now being tested in a phase III trial of up-front androgen deprivation plus orteronel vs. androgen deprivation alone for metastatic hormone-sensitive prostate cancer, it does not have an FDA-approved indication for any setting.

Androgen Receptor Modulation: Enzalutamide, Apalutamide, and Other Agents

A slightly different AR-directed approach has focused on the development of next-generation antiandrogens that include advantages beyond the established agents in this class (bicalutamide, nilutamide, flutamide). One such drug is enzalutamide, a potent oral nonsteroidal AR antagonist (Chen et al., 2009). Importantly, enzalutamide remains a strong antagonist of the AR in the castration-resistant state, even in the setting of overexpressed or constitutively activated AR (Watson et al., 2010). Unlike other antiandrogens that may also function as partial AR agonists, enzalutamide does not exhibit any measurable agonistic activity. In addition to acting as an AR blocker, enzalutamide also disrupts the translocation of the AR from the cytoplasm (where it is inert) into the nucleus (where it acts as a transcription factor), while also impairing binding of the AR to the transcriptional complex at the androgen-response elements of DNA (Tran et al., 2009). One potential advantage of enzalutamide over abiraterone is the lack of a requirement for concurrent corticosteroid administration. In fact, data suggest that enzalutamide may potentially be less active if administered together with prednisone, perhaps because of promiscuous activation of AR by prednisone or by direct agonism of the glucocorticoid receptor (Scher et al., 2013).

A pivotal placebo-controlled double-blind phase III study (AFFIRM), randomizing 1199 patients with docetaxel-pretreated ketoconazole-naive CRPC to enzalutamide ($n = 780$) or placebo ($n = 390$), was conducted to examine the effect of enzalutamide on overall survival. Patients receiving up to 2 previous lines of chemotherapy (one of which must have contained docetaxel) were the target population. The trial showed a 4.8-month improvement in median survival with enzalutamide compared with placebo (18.4 months vs. 13.6 months, HR 0.63, *P* < 0.0001) (Fig. 162.6; Scher et al., 2012). A survival benefit was observed in all prespecified subgroups, although less benefit was seen in those with ECOG performance status of 2, similar to what was observed in the abiraterone trials. Confirmed PSA declines of more than 50% were seen in 54.0% compared with 1.5% (*P* < 0.0001) of patients receiving enzalutamide and placebo, respectively. Median time to progression was 8.3 compared with 3.0 months in the two arms (HR 0.25, *P* < 0.0001). Side effects were minimal and included fatigue, diarrhea, and hot flashes. Seizures were observed in about 1% of enzalutamide-treated patients. Based on the results of the AFFIRM trial, the FDA approved enzalutamide in August 2012 for the treatment of mCRPC in patients who have previously received docetaxel-containing chemotherapy.



No. at risk									
Enzalutamide	800	775	701	627	400	211	72	7	0
Placebo	399	376	317	263	167	81	33	3	0

FIG. 162.6 Overall survival in the AFFIRM study. (Data from Scher HI, Fizazi K, Saad F, et al.: Increased survival with enzalutamide in prostate cancer after chemotherapy. *N Engl J Med* 367:1187–1197, 2012.)

To evaluate the efficacy of enzalutamide in the pre-chemotherapy setting, the PREVAIL study was designed. This was a phase III double-blind placebo-controlled trial in 1717 chemotherapy-naive patients with asymptomatic or minimally symptomatic mCRPC who were randomized (1 : 1) to oral enzalutamide or placebo. At the time of an interim analysis, the study met its coprimary end points of radiographic PFS and overall survival. Compared with placebo, treatment with enzalutamide in the pre-chemotherapy setting resulted in a 29% reduction in the risk of death (HR 0.71, 95% CI 0.60–0.84, $P < 0.0001$) and an 81% reduction in the risk of radiographic progression (HR 0.19, 95% CI 0.15–0.23, $P < 0.0001$) (Beer et al., 2014). Based on the results of the PREVAIL trial, the FDA expanded its label to allow use of enzalutamide in all patients with mCRPC, regardless of whether they have received prior docetaxel.

Finally, the most recent pivotal trial of enzalutamide was the PROSPER study, a phase III trial of enzalutamide vs. placebo in men with nonmetastatic (M0) CRPC with a PSADT of less than 10 months. In that study, enzalutamide was shown to dramatically improve metastasis-free survival, the primary endpoint of the trial, by an impressive 71% (HR 0.29, 95% CI 0.24–0.35; $P < 0.001$) (Hussain et al., 2018). Overall survival was also numerically improved, although not statistically greater, in the enzalutamide rather than the placebo arm. Based on the positive outcome of the PROSPER trial, the FDA label of enzalutamide was expanded again in July 2018 to include any patients with CRPC, regardless of whether they have radiographic metastases identified. This is the broadest label for an antiandrogen drug that the FDA has granted.

Another next-generation AR signaling inhibitor is apalutamide (formerly ARN-509). This is a novel antiandrogen (similar to enzalutamide) that also functions as a pure antagonist of the AR, while also inhibiting AR nuclear translocation and DNA binding (Clegg et al., 2012). Apalutamide may include potential advantages over enzalutamide in that it does not cross the blood-brain barrier and it has not been associated with seizures. Early evidence of clinical activity was obtained from a phase I study in 30 patients with progressive CRPC who received continuous daily oral apalutamide at doses between 30 and 480 mg; a maximum efficacious dose of 240 mg daily was selected for phase II testing (Rathkopf et al., 2013). Adverse events with apalutamide included fatigue (47%), diarrhea (30%), headache (20%), and hot flashes (13%). A phase II study of apalutamide was then conducted, which enrolled three separate patient cohorts: men with nonmetastatic CRPC, men with mCRPC, and men with abiraterone-pretreated mCRPC (Rathkopf et al., 2012). In all three cohorts, a significant proportion of PSA responses gave evidence to clinical activity (although these responses were less frequent in each successive cohort as a result of more advanced disease).

This agent was then studied in the pivotal SPARTAN trial, a multicenter blinded randomized phase III study for patients with nonmetastatic CRPC, in which metastases-free survival was selected as the primary end point. In that study, patients with M0 CRPC and a PSADT of less than 10 months were randomized (2 : 1) to either apalutamide or placebo. Notably, the SPARTAN trial met its primary end point of delaying metastasis-free survival by an impressive 72% (HR 0.28, 95% CI 0.23–0.35; $P < 0.001$) (Smith et al., 2018), with a similar trend in overall survival. Time to symptomatic progression was also longer with apalutamide than with placebo (HR 0.45, 95% CI 0.32–0.63, $P < 0.001$). The rate of adverse events leading to drug discontinuation was 10.6% in the apalutamide group and 7.0% in the placebo group. Side effects that occurred more commonly in the apalutamide arm included rash (24% vs. 6%), hypothyroidism (8% vs. 2%), falls (16% vs. 9%), and fractures (12% vs. 6%). Based on the impressive efficacy and favorable toxicity profile, the FDA approved apalutamide in February 2018 for the treatment of M0 CRPC, the first approval of its kind for this disease space. However, it must be remembered that apalutamide does not have approval for use in metastatic prostate cancer at this time.

AR-V7: A Potential Treatment-Selection Marker

One molecular biomarker that may aid appropriate selection of therapy (i.e., AR-directed therapy vs. taxane chemotherapy) for patients with CRPC is the presence of androgen receptor splice variant 7 (AR-V7) in circulating tumor cells (CTCs) (Antonarakis et al., 2016). AR-V7 is a splicing variant of the androgen receptor that lacks the ligand-binding domain yet remains constitutively active as a transcription factor in a ligand-independent manner. Lack of response of men with CRPC to abiraterone and enzalutamide was associated with detection of AR-V7 mRNA in CTCs using an mRNA-based polymerase chain reaction (PCR) assay (Antonarakis et al., 2014). However, AR-V7 presence did not preclude clinical benefit from taxane chemotherapies (docetaxel and cabazitaxel) (Antonarakis et al., 2015). Men with AR-V7(+) CTCs exhibited superior PFS with taxanes compared with novel hormonal therapies (abiraterone and enzalutamide); however, the two classes of agents resulted in comparable PFS in men with AR-V7(–) CTCs. A confirmatory study used a different CTC assay that detected nuclear-localized AR-V7 protein using an immunofluorescence approach. Men with AR-V7(+) CTCs in that study had superior overall survival with taxanes versus abiraterone or enzalutamide, whereas survival was not different between the two classes of agents among patients with AR-V7(–) CTCs (Scher et al., 2016). These data perhaps suggest that men with AR-V7(+) mCRPC may respond more favorably to taxane agents, whereas those with AR-V7(–) mCRPC may benefit equally from AR-directed agents or taxane chemotherapies.

These single-center clinical experiences suggest that AR-V7 assays are promising predictors of abiraterone and enzalutamide resistance (and not taxane resistance), but they have not yet been validated prospectively and externally. Furthermore, the prevalence of AR-V7 positivity is only 3% to 10% in patients who have not yet received treatment with enzalutamide, abiraterone, or taxanes (Antonarakis et al., 2017; Scher et al., 2016), so the authors believe that AR-V7 detection may not be useful to inform treatment decisions in the treatment-naive CRPC setting. On the other hand, the prevalence of AR-V7 positivity is higher after progression on abiraterone or enzalutamide (20% to 40%) (Antonarakis et al., 2017; Scher et al., 2016), and therefore the clinical utility of this biomarker may be best demonstrated in this clinical setting (where the choice between sequential AR-directed therapies or switching to taxane chemotherapies is being entertained). Several prospective trials aiming to validate the AR-V7 biomarker are underway.

Key Points: Next-Generation Hormonal Therapies

- There is mounting evidence that CRPC is not androgen-independent and continues to rely on androgen/AR signaling.
- Abiraterone is a CYP17 inhibitor that depletes adrenal and intratumoral androgens. It is approved for the treatment of mCRPC before and after chemotherapy (but not for nonmetastatic CRPC).
- Enzalutamide is an AR signaling inhibitor that antagonizes the AR and prevents nuclear translocation and DNA binding. It was shown to improve survival in men with mCRPC in the prechemotherapy and postchemotherapy settings and to improve metastasis-free survival for men with M0 CRPC. Enzalutamide is approved for any patient with CRPC, regardless of metastatic status.

- Apalutamide is a second AR signaling inhibitor that has shown superiority to placebo in men with nonmetastatic (M0) CRPC and has received approval for this indication. Apalutamide is not approved for use in metastatic CRPC.
- Additional CYP17-inhibiting agents (e.g., orteronel) and AR-targeting agents (e.g., darolutamide) are in clinical development.
- AR-V7 is a blood-based biomarker that may be used to aid in the choice of therapy for mCRPC patients. AR-V7(+) patients may benefit more from taxane chemotherapy, whereas AR-V7(–) men may benefit similarly from either AR-directed therapy or chemotherapy.

Immunotherapy

An alternative or complementary strategy for the treatment of prostate cancer involves the use of immune-active agents. Cancer immunotherapy refers generally to approaches that attempt to treat cancer by activating immune responses against malignant cells while overcoming tumor-induced tolerance (Drake, 2010). Although not traditionally considered a disease amenable to immune-directed therapies, prostate cancer may in fact be an ideal target for immunologic attack because it is a slow-growing disease (allowing a stimulated immune system the time to generate an antitumor response), and it produces several tissue-specific proteins that may serve as tumor antigens: these include PSA, prostatic acid phosphatase (PAP), and others.

Entraining the immune system to overcome tumor-induced tolerance is the goal of nearly every cancer vaccine program, and active immunotherapy with vaccination against tumor-specific antigens has been pursued in many different cancer models including prostate cancer. A variety of approaches have been used, including dendritic cell–based therapies, adjuvants such as granulocyte-macrophage colony-stimulating factor (GM-CSF), viral carriers, single-antigen or whole-cell vaccines, genetically modified tumor cell vaccines, and DNA plasmid vaccines. More recently, strategies incorporating costimulatory molecules, cytotoxic T-lymphocyte antigen–4 (CTLA-4) blockade, PD-1 blockade, and intracellular viral or bacterial mediators have also been developed (Blattman et al., 2002; Drake, 2010; Harzstark and Small, 2009; Mapara and Sykes, 2004; Webster et al., 2005).

In prostate cancer, several of these immunologic approaches have been under clinical investigation, the most important of which is sipuleucel-T (an autologous PAP-loaded dendritic cell vaccine), which has gained FDA approval for patients with asymptomatic or minimally symptomatic mCRPC. Other immunotherapies that have entered late-phase clinical development include the GVAX allogeneic recombinant whole-cell vaccine (which failed to meet its primary end point in phase III trials), the ProstVac-VF recombinant poxviral PSA vaccine (currently in phase III testing), and CTLA-4 inhibitory approaches including ipilimumab (also in phase III testing).

Sipuleucel-T

Sipuleucel-T (Provenge) is a personalized vaccine that is derived from autologous CD54+ dendritic cells, the major class of antigen-presenting cells, which are apheresed from individuals and processed with a recombinant fusion protein composed of PAP and GM-CSF. PAP was chosen based on its prostate cell membrane localization and the success of preclinical models using it to generate prostate-specific immune responses and autoimmune prostatitis. Mixed activity was initially reported in early-phase trials using sipuleucel-T in patients with CRPC. In a randomized phase II/III trial comparing sipuleucel-T against placebo in 127 asymptomatic men with mCRPC, there was no significant difference in time to disease and pain progression ($P = 0.052$), which was the primary study end point (Small et al., 2006). However, patients randomized to placebo could cross over to receive the active vaccine at the time of progression, whereas those initially randomized to receive the active vaccine were treated at their physician's discretion at the time of progression. A 3-year update of this trial suggested a statistically significant improvement in overall survival for those patients assigned to receive sipuleucel-T initially ($P = 0.01$). Post hoc analyses also suggested that the benefits of sipuleucel-T may be limited to the subgroup of men with tumor Gleason sums of 7 or lower. Although preparation and production of large-scale quantities of individually tailored vaccine can be challenging, this vaccine was well tolerated, with minimal infusion-related fevers and rigors being the predominant adverse events (Small et al., 2006).

A second phase II/III trial that randomized 98 men with asymptomatic CRPC to either sipuleucel-T or placebo also failed to show a statistically significant improvement in time to progression (the primary end point of this study). However, post hoc pooled analyses of these two trials ($n = 225$) did show an overall survival advantage, with median survival being 18.9 months in the placebo group and 23.2 months in the sipuleucel-T group (HR 0.67, 95% CI 0.49–0.91, $P = 0.01$) (Higano et al., 2009). However, because overall survival was not the primary end point in either of these two trials, the FDA (justifiably) did not grant approval of this treatment at that time.

To evaluate definitively the clinical usefulness of sipuleucel-T in a larger patient population, a pivotal multicenter double-blind placebo-controlled randomized phase III trial (IMPACT) was conducted in men with asymptomatic or minimally symptomatic mCRPC (Kantoff et al., 2010a), finally leading to the FDA approval of this agent in April 2010. In this trial, 512 patients were randomized (2 : 1) to sipuleucel-T or to placebo, and the study was powered to detect an overall survival advantage. Notably, this study did not enroll men with visceral metastases or those taking narcotics for cancer pain, and most patients (85%) were chemotherapy naive. Impressively, median overall survival was 25.8 months in the sipuleucel-T group versus 21.7 months in the placebo group (HR 0.78, $P = 0.03$) (Fig. 162.7), despite 64% of patients on placebo crossing over to receive salvage sipuleucel-T at the time of disease progression. In the subset of patients with previous chemotherapy exposure, overall survival trended in favor of sipuleucel-T, but this effect was not statistically significant. Therefore, although this immunotherapy is approved for all patients with asymptomatic or minimally symptomatic CRPC, it will likely provide its largest impact in the pre-chemotherapy setting. In addition, it should not be used in patients with visceral disease or in those requiring narcotic analgesics for cancer-related pain.

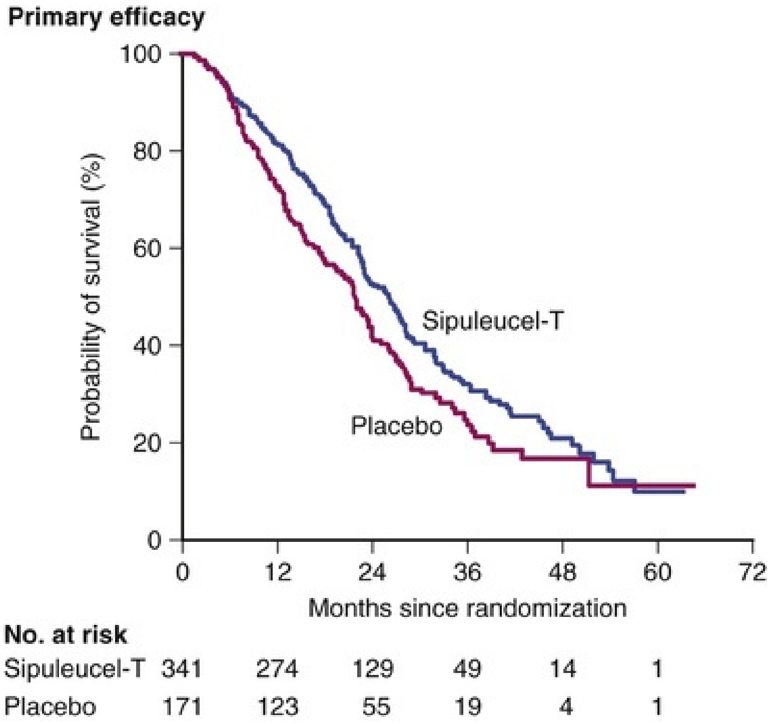


FIG. 162.7 Overall survival in the IMPACT study. (Data from Kantoff PW, Higano CS, Shore ND, et al.: Sipuleucel-T immunotherapy for castration-resistant prostate cancer. *N Engl J Med* 363:411–422, 2010.)

Similar to previous studies with sipuleucel-T, the IMPACT study detected no difference in PFS or PSA/radiographic response rates between the two treatment arms. Some investigators attribute the discord between progression-free and overall survival to a possible class effect of immunotherapy agents relating to their mechanism of action, which is distinct from cytotoxic therapies.

Problematic end points such as PFS in CRPC (which may be confounded by bone scan flare or delayed-onset effects) may perhaps be better addressed by revised guidelines using outcomes that are tailored to immunologic agents (Hoos et al., 2010). These new immune-related response criteria may help in the future development of additional immunotherapy agents for prostate cancer and other malignancies.

Because of the notion that immunotherapies are likely to have their biggest impact in the early disease setting, sipuleucel-T has also been tested in combination with ADT in men with nonmetastatic biochemically recurrent prostate cancer (Antonarakis and Kibel, 2013). Although the immunologic data from this trial appear encouraging, the mature clinical results are still awaited. In addition, other trials are currently testing the combination of sipuleucel-T with other AR-directed therapies. For example, one trial is examining the combination and sequencing of sipuleucel-T with abiraterone in men with mCRPC. Another trial is evaluating the optimal combination and sequencing of sipuleucel-T with enzalutamide. Both of these studies have not yet produced mature results. However, it is likely that immunotherapies will be combined routinely with other standard prostate cancer therapies moving forward so as to maximize clinical outcomes, especially if these agents do not have overlapping toxicities.

ProstVac-VF

ProstVac-VF is a PSA-targeted poxviral-based vaccine approach that has been developed through a series of iterative preclinical and clinical studies. The final version uses a heterologous prime-boost strategy (vaccinia prime, fowlpox boost) and incorporates a DNA plasmid containing the PSA gene plus three costimulatory molecules serving to increase PSA-specific immune responses (Madan et al., 2009). This particular vaccine is not a personalized product, is relatively inexpensive to synthesize, and is administered by repeated subcutaneous injections throughout several months. Similar to the clinical experience with sipuleucel-T, a randomized phase II study using this immunotherapy product demonstrated improved overall survival (a secondary end point) among men with mCRPC who received ProstVac-VF compared with those receiving an empty-vector placebo (25.1 vs. 16.6 months, HR 0.56, P = 0.006), whereas there was no impact on the primary end point of PFS (Kantoff et al., 2010b).

After from these encouraging results, and recognizing that this class of agents may produce a survival benefit without altering radiographic progression, a multinational randomized phase III trial (PROSPECT) was launched in which 1297 men with chemotherapy-naive asymptomatic or minimally symptomatic mCRPC were allocated (1 : 1 : 1) to one of three treatment arms: ProstVac-VF administered alone, ProstVac-VF plus subcutaneous GM-CSF, or double-placebo. The primary end point of this pivotal trial was overall survival. Unfortunately, the final results of this trial were recently presented and there was no survival advantage observed for either of the ProstVac-VF–containing arms over placebo (Gulley et al., 2018). There were also no differences seen in any of the secondary efficacy end points.

However, there has been considerable interest in combining ProstVac-VF with other standard prostate cancer therapies in earlier disease settings. In a completed phase II study involving 42 men with nonmetastatic CRPC, patients were randomized to ProstVac-VF, followed by nilutamide versus nilutamide, followed by ProstVac-VF (Madan et al., 2008). This study suggested a potential improvement in overall survival in men receiving ProstVac-VF before nilutamide rather than the opposite sequence (6.2 vs. 3.7 years, $P = 0.04$). Another randomized phase II trial currently compares the combination of ProstVac-VF plus enzalutamide versus enzalutamide alone in men with biochemically recurrent prostate cancer. Finally a separate randomized phase II study compares ProstVac-VF plus enzalutamide versus enzalutamide alone in men with mCRPC. These studies may help to elucidate the role of combination immunohormonal therapy in various prostate cancer clinical states, although the fate of ProstVac-VF is uncertain.

Immune Checkpoint Blockade

Because of ongoing host immunologic pressures on evolving tumors, cancers have developed mechanisms to escape immune surveillance, effectively inducing a state of immune tolerance (Drake et al., 2006). One way to inhibit immunologic evasion by tumor cells is through the blockade of the immune checkpoint molecule CTLA-4 (cytotoxic T lymphocyte-associated antigen-4), thus preventing the normal attenuation of antitumor T-cell responses (Hodi, 2007). In murine prostate cancer models, CTLA-4 inhibition has been shown to potentiate T-cell effects and to induce tumor rejection including at metastatic sites (Kwon et al., 1999).

Several clinical trials using the monoclonal anti–CTLA-4 antibody, ipilimumab, have been conducted in men with mCRPC. These include phase I and II studies of ipilimumab monotherapy or therapy in combination with radiation (Small et al., 2007), as well as a phase I study combining ipilimumab with GM-CSF (Fong et al., 2009). Encouragingly, across a broad range of phase I and II studies, greater than or equal to 50% of PSA reductions have been observed in about 10% to 20% of prostate cancer patients, and radiologic tumor responses were seen in about 5% of men (Slovin et al., 2013), which is particularly noteworthy given that PSA and tumor responses were rarely reported in the immunotherapy trials with sipuleucel-T or other therapeutic vaccines. Common side effects of ipilimumab include fatigue (42%), nausea (35%), pruritus (24%), constipation (21%), and rash (19%). In addition, because CTLA-4 normally attenuates autoimmunity, immunologic toxicities resulting from an unchecked immune response may occur. Such immune-related adverse events include colitis (15% to 20%), hepatitis (5%), adrenal insufficiency and other endocrinopathies (2%), dermatitis/vitiligo (2%), and even hypophysitis (1%) (Dillard et al., 2010; Drake et al., 2014).

Based on these encouraging phase II data, ipilimumab entered phase III testing in the pre- and post-chemotherapy settings. The first trial to be completed was a placebo-controlled phase III study in 799 men with mCRPC who had previously received docetaxel-based chemotherapy: all patients received a low dose of immune-stimulatory radiotherapy to a bone metastasis (8 Gy) followed by treatment allocation to either ipilimumab (administered intravenously every 3 weeks for 12 weeks, and then every 12 weeks thereafter) or matching placebo. In this trial, although treatment with ipilimumab was associated with superior PSA response rates (13.1% vs. 5.3%, $P = 0.001$) and improved PFS (HR 0.70, 95% CI 0.61–0.82, $P < 0.0001$), there was no statistically significant improvement in overall survival although there was a strong trend favoring the ipilimumab arm (HR 0.85, 95% CI 0.72–1.00, $P = 0.053$) (Drake et al., 2014). Patients without visceral disease experienced the greatest benefit from ipilimumab, as well as those patients with normal hemoglobin and alkaline phosphatase levels. A second pre-docetaxel placebo-controlled phase III study that enrolled 600 patients was also recently reported. In this trial, men with asymptomatic or minimally symptomatic CRPC were randomized to ipilimumab or placebo; overall survival was the primary end point. Unfortunately, this study also failed to show an improvement in patient lifespan among those receiving ipilimumab versus placebo (HR 1.11, 95% CI 0.88–1.39, $P = 0.37$) (Beer et al., 2017), although PFS was prolonged with ipilimumab and there were several patients who achieved PSA responses and objective tumor responses. This suggests that a subset of mCRPC patients may benefit from ipilimumab treatment, although the unselected population as a whole does not derive benefit.

Pembrolizumab for Microsatellite Instability-High Cancers

In May 2017 the FDA approved the use of the anti–PD-1 antibody, pembrolizumab, for treatment of patients with “unresectable or metastatic microsatellite instability-high (MSI-H) or mismatch repair-deficient (dMMR) solid tumors who have progressed on prior treatments and who have no satisfactory alternative treatment options” (Keytruda, 2017). The recommended adult dosage of pembrolizumab for this indication is 200 mg given intravenously once every 3 weeks. Approval was based on the treatment of 149 patients across 5 clinical studies involving MSI-H or dMMR colorectal (n = 90) or non-colorectal (n = 59) cancers, demonstrating an objective response rate of 40% (59/149) (Keytruda, 2017). All patients received at least 1 prior systemic regimen. Among the non-colorectal cohorts, 2 patients had metastatic CRPC: one achieved a partial objective response with pembrolizumab, and the other achieved stable disease for more than 9 months.

A total of 11 additional patients with metastatic CRPC treated with pembrolizumab have been reported (Graff et al., 2016; Le et al., 2017). In one study, only 1 patient had dMMR prostate cancer (Le et al., 2017). He had treatment-refractory, progressive, mCRPC and experienced a complete response with pembrolizumab. In the other study, 10 patients with mCRPC and biopsiable metastases (bone = 7; lymph nodes = 2; bone and liver = 1) who had disease progression on enzalutamide were treated with pembrolizumab and concurrent enzalutamide (Graff et al., 2016). Three of the 10 patients showed a near-complete PSA response. Two of these 3 patients had radiographically measurable disease and also achieved a partial radiographic response (including a response in liver metastases). Genetic analysis of biopsy tissue revealed that one responder had a dMMR/MSI-H tumor, whereas the other responder and the non-responders did not.

The most common adverse events from pembrolizumab are fatigue, pruritus, diarrhea, anorexia, constipation, nausea, rash, fever, cough, dyspnea, and musculoskeletal pain. Pembrolizumab also may be associated with immune-mediated side effects, which include colitis, hepatitis, endocrinopathies, pneumonitis, and nephritis.

Based on the available data, the authors support the use of pembrolizumab in patients with MSI-H or dMMR metastatic CRPC whose disease has progressed through at least one line of systemic therapy for mCRPC (e.g., abiraterone or docetaxel). The prevalence of MMR deficiency in metastatic CPRC is estimated at 2% to 5% (Le et al., 2017; Robinson et al., 2015), and testing for MSI-H or dMMR can be performed using next-generation DNA sequencing or immunohistochemistry for the MMR proteins (MSH2, MSH6, MLH1, and PMS2). If a tumor is found to have MSI-H and/or dMMR, the authors also recommend referral to genetic counseling for consideration of germline testing for Lynch syndrome (hereditary non-polyposis colorectal cancer).

Key Points: Immunotherapy

- Sipuleucel-T was the first therapeutic vaccine to be approved by the FDA for the treatment of any cancer, and it is indicated for men with asymptomatic or minimally symptomatic mCRPC without visceral metastases or cancer-related pain requiring narcotics.
- ProstVac-VF is a poxviral-based PSA-directed prostate cancer vaccine that is administered by subcutaneous injection. The phase III PROSPECT trial failed to show an improvement in survival, calling into question the role of this immunotherapy.
- Ipilimumab did not show prolongation in survival either in the post-docetaxel or the pre-docetaxel settings and did not receive FDA approval for use in mCRPC, although some patients achieved objective tumor responses suggesting a potential benefit in a small subset of patients; ipilimumab should not be used routinely in clinical practice.
- Pembrolizumab is a PD-1 inhibitor that is indicated for mCRPC patients with a MSI-high and/or MMR-deficient phenotype, although this may only reflect 2% to 5% of prostate cancers.
- The future of prostate cancer immunotherapies is likely to involve their use in the early disease setting or in combination with other standard prostate cancer therapeutics (hormone therapy, chemotherapy, or radiotherapy).

Targeted Treatments

Rational Target Overview

An understanding of the basic biology involved in the pathogenesis and progression of prostate cancer provides the opportunity to identify potential therapeutic targets for this disease. In general terms, the first therapeutic opportunity is the demonstration of a mutation or functional dysregulation of a target. Simply targeting overexpressed proteins has been less effective than the specific targeting of mutations that drive the bulk of the tumor growth. However, with the exception of the AR, this scenario is rare in prostate cancer. The second goal is identifying target causality, indicating the importance of the target alone or in combination with other aberrations in reproducing the phenotypic findings of prostate cancer. Finally there should be evidence from preclinical models that inhibition of the target leads to tumor regression or quiescence, not just growth restriction.

In prostate cancer, the AR is one potential therapeutic target, although there are many others. Given the molecular complexity of the prostate cancer cell and the relatively poor understanding of the role of non-AR pathways in prostate cancer progression and metastasis, the simultaneous inhibition of multiple pathways remains a common strategy to induce sustained and clinically meaningful patient responses. In addition, although a prostate cancer stem cell has yet to be conclusively demonstrated, prostate cancer clearly progresses from an androgen-dependent tumor (with features similar to the luminal differentiated glands of the prostate) to an AR-independent tumor (that has features of adult stem cells, including antiapoptotic mechanisms, chemotherapy resistance, and reliance on non-AR–related pathways).

To this end, candidate pathways currently under evaluation as targets for prostate cancer treatment include phosphatidylinositol 3-kinase (PI3K)/Akt/mammalian target of rapamycin (mTOR) signaling, epidermal growth factor receptor (EGFR) signaling, mitogen-activated protein kinase (MAPK) signaling, angiogenesis signaling, apoptosis signaling, hedgehog signaling, insulin-like growth factor receptor (IGF-1R) signaling, Src kinase signaling, endothelin signaling, and several others (Wozney and Antonarakis, 2014). However, therapeutic approaches targeting these pathways have been largely unsuccessful, with few exceptions. Here we outline some of the most promising efforts relating to therapies targeting the Akt/mTOR pathway, angiogenesis, and MET signaling, as well as apoptotic pathways. This section provides an overview of these select pathways as they pertain to prostate cancer rational targets and the approaches that are currently being developed for therapeutic purposes.

PI3K/Akt/mTOR Pathway

The PI3K/Akt/mTOR pathway is an important signaling cascade present in many different types of human cancer. This pathway has been linked to cell survival, differentiation, proliferation, growth, metabolism, migration, and angiogenesis. Normally, signaling via this pathway begins with the binding of a growth factor to a receptor tyrosine kinase resulting in downstream activation of PI3K. Alternatively, PI3K activation can occur via Ras through G-protein–coupled receptors. PI3K phosphorylates its substrate, phosphatidylinositol 4,5-bisphosphate (PIP2) to produce phosphatidylinositol 3,4,5-triphosphate (PIP3). PIP3 can proceed to bind to various signaling proteins and can initiate downstream signaling via Akt. This pathway is negatively regulated by the protein tyrosine phosphatase (PTEN) (often deleted in prostate cancer), which dephosphorylates PIP3 to PIP2, thereby terminating further signaling (Courtney et al., 2010; Engelman, 2009). The PI3K/Akt signaling cascade promotes cell survival and resistance to apoptosis through several different mechanisms, including interactions with the Bcl-2 family members BAD and BAX, nuclear factor-κB (NF-κB), and Mdm2. Also downstream of this pathway is the mTOR protein. Activation of mTOR leads to increased protein synthesis through phosphorylation of ribosomal proteins and translation elongation factors. In this fundamental way, mTOR is an important modulator of cell growth. Multiple feedback loops and regulators control mTOR signaling, and the pathway integrates inputs from various metabolic, growth factor, and survival pathways (Dancey, 2010).

Laboratory data have provided compelling foundations for studying the role of inhibitors of PI3K and its downstream targets in prostate cancer. Taylor et al. (2010) performed genomic profiling of 218 primary or metastatic prostate cancers, integrating information about DNA copy number, mRNA expression profiles, and exon sequencing. A core pathway analysis showed that altered signaling in the PI3K pathway was present in nearly half of all primary prostate tumors and in virtually all metastatic tumors tested. About 40% of all cases demonstrated loss-of-function of PTEN through deletion, inactivating mutation, or reduced expression. In contrast to many other cancers, activating mutations in the *PIK3CA* gene were rare. However, loss-of-function mutations in the regulatory subunits PIK3R1 and PIK3R3 were prevalent, suggesting another mechanism for constitutive activation of PI3K in prostate cancer (Taylor et al., 2010).

Despite these telling observations, attempts to target segments of the PI3K/Akt/mTOR pathway in prostate cancer patients have been modest. Studies of the mTOR inhibitors rapamycin, everolimus, and temsirolimus as single agents and in combination with the AR antagonist bicalutamide failed to demonstrate significant clinical activity in mCRPC (Amato et al., 2008; Armstrong et al., 2013; Nakabayashi et al., 2012). Nevertheless, based on preclinical data showing that mTOR inhibition can reverse chemotherapy resistance in PTEN-deficient prostate cancer cell lines, ongoing trials are examining the efficacy of combined treatment with mTOR inhibitors and docetaxel (Duran et al., 2012; Grunwald et al., 2002). Other novel mTOR inhibitors and combination therapies are also under investigation.

One possible explanation for the failure of single-agent mTOR inhibitors to show efficacy in prostate cancer is the hypothesis that mTOR blockade leads to feedback-driven upregulation of signaling molecules upstream in the PI3K pathway. Studies by Carver et al. (2011) have demonstrated the existence of bidirectional crosstalk between PI3K signaling and AR signaling. For example, in a preclinical model, inhibition of the PI3K pathway resulted in activation of AR signaling in PTEN-deficient prostate cancer cells. Similarly, the AR antagonist enzalutamide appeared to upregulate Akt signaling by reducing levels of the regulatory phosphatase PHLPP (PH domain leucine-rich repeat protein phosphatase). Combined blockade with the dual PI3K/mTOR inhibitor, BEZ235, and enzalutamide led to reductions in tumor size in human prostate cancer xenograft models (Carver et al., 2011). This work provides a sound rationale for simultaneous targeting of both pathways.

Under this premise, BEZ235 currently is being studied in combination with abiraterone in men with advanced CRPC. A first-in-human phase I study (which enrolled patients with various solid tumors) showed that BEZ235 was tolerable because no DLTs were observed in the doses tested. Frequently reported side effects were fatigue and gastrointestinal symptoms. A few tumor responses were seen; patients whose tumors demonstrated activated PI3K pathway signaling were the most likely to respond to treatment with BEZ235. Because of pharmacokinetic variability, the drug was reformulated to improve bioavailability, which initially delayed clinical development of this agent (Burris et al., 2010; Maira et al., 2008).

Efforts to develop the potent and specific Akt inhibitor, MK2206, are also seeking to capitalize on the preclinical observations that simultaneous AR blockade and PI3K pathway inhibition may be synergistic. Previous phase II studies of another putative inhibitor of Akt, perifosine, had been disappointing. However, correlative pharmacodynamic studies were not performed in perifosine-treated patients, and therefore it is unclear whether target inhibition was actually achieved in these studies (Chee et al., 2007; Posadas et al., 2005). Conversely, pharmacodynamic correlates to the phase I study that established the safety profile and maximum tolerated dose of MK2206 have confirmed its ability to target and inhibit Akt in humans. The most frequent side effects of MK2206 are hyperglycemia, nausea, diarrhea, skin rash, and stomatitis (Yap et al., 2011). Another Akt inhibitor, ipatasertib, is currently being studied in combination with abiraterone (de Bono et al., 2019). To this end, in the phase III IPATential150 trial, 1100 patients with mCRPC and PTEN deficiency will be randomized to abiraterone alone or in combination with oral ipatasertib; the primary end point of this trial is to improve radiographic PFS. The most common adverse events associated with ipatasertib include diarrhea, nausea, vomiting, asthenia, rash, decreased appetite, and hyperglycemia.

Angiogenesis

Therapeutic strategies aimed at preventing the growth of tumor vasculature have yielded clinical benefits for patients with several types of cancers, most notably renal cell carcinoma. There is a strong preclinical basis for studying inhibitors of angiogenesis in prostate cancer because this process appears to play an important role in prostate carcinogenesis and maintenance. One of the key factors in angiogenesis is hypoxia-induced factor-1α (HIF-1α), a transcription factor whose expression is regulated by oxygen levels and growth factor signaling. HIF-1α controls expression of various genes, including many that are involved in angiogenesis, such as VEGF. VEGF acts directly on endothelial cells to stimulate proliferation and to increase vascular permeability, forming the matrix on which neovascularization can occur. In this manner, hypoxia-dependent and hypoxia-independent mechanisms can induce angiogenesis (Semenza, 2003). In prostate cancer, neovascularization is triggered not only by the hypoxic tumor microenvironment but also by aberrant growth factor signaling. For example, prostate cancer cells may aberrantly express the VEGF receptor and ligand. This suggests a dual role for this pathway, involving paracrine signaling, which promotes angiogenesis, and autocrine signaling, which stimulates cell growth and proliferation (Ferrer et al., 1997, 1999).

Many drugs that inhibit VEGF signaling have been tested in prostate cancer, including several that have been FDA approved for treatment of other solid tumors. The best known is bevacizumab, a humanized monoclonal antibody to VEGF. Bevacizumab was evaluated in a phase III cooperative group trial in patients with mCRPC. Participants were treated with docetaxel and either bevacizumab (15 mg/kg IV every 21 days) or placebo. More than 1050 patients were enrolled in the study. PFS improved in the bevacizumab arm (9.9 vs. 7.5 months, $P < 0.001$), but overall survival did not differ significantly between arms (22.6 vs. 21.5 months, $P = 0.18$) (Kelly et al., 2012). Grade-3 or higher toxicities were more common in the bevacizumab arm, as was treatment-related mortality. Serious adverse events attributed to bevacizumab included hypertension, gastrointestinal perforation/hemorrhage, mucositis, and pneumonitis. Based on the “negative” results of this study, the FDA has not approved bevacizumab for use in patients with advanced prostate cancer. Ongoing studies are evaluating its role in conjunction with a short course of ADT in the PSA-recurrent/nonmetastatic setting. It is also being studied in mCRPC patients in combination with the mTOR inhibitors everolimus and temsirolimus.

An alternative antiangiogenic strategy involves the use of the VEGF-trap molecule aflibercept. Aflibercept is a decoy receptor that binds circulating VEGF ligand, thereby preventing its association with cellular VEGF receptors. The drug was studied in a multinational phase III trial in symptomatic mCRPC patients. More than 1200 patients were randomized to receive docetaxel plus either aflibercept or placebo. In this trial, there were no significant differences in progression-free or overall survival, and toxicities were higher in the aflibercept arm (Tannock et al., 2013). The increase in toxicities in the interventional arm mimicked the higher rate of adverse events with the docetaxel-bevacizumab combination. Because of these negative findings, no further studies of aflibercept are planned in patients with prostate cancer.

Attempts to target VEGF signaling with small molecule inhibitors in men with prostate cancer have shown some promise in phase II studies, but only one of these agents (sunitinib) has entered phase III testing. Sunitinib is a promiscuous tyrosine kinase inhibitor that blocks VEGFR2 and platelet-derived growth factor-β. A phase III study was conducted in patients with mCRPC who progressed after docetaxel chemotherapy. In this trial, more than 870 men were randomized to single-agent sunitinib or placebo. Although PFS was superior for sunitinib (5.6 vs. 4.1 months, $P < 0.001$), there was no significant difference in overall survival compared with placebo (13.1 vs. 11.8 months, $P = 0.17$) (Michaelson et al., 2014). The results of this study also raise the question of whether an overall survival benefit may have been observed if sunitinib had been continued beyond radiographic progression in patients who were tolerating the drug well. This agent is not FDA approved for prostate cancer.

Despite the disappointing results from the aforementioned phase III trials, several drugs targeting angiogenesis in novel ways remain in clinical development. Perhaps the most promising of these is tasquinimod, a second-generation quinolone-3-carboxamide analogue. Tasquinimod inhibits angiogenesis by preventing the upregulation of HIF-1α and the resultant aberrant VEGF expression. It also appears to induce expression of an endogenous antiangiogenesis factor, thrombospondin-1. Through an alternative or complementary mechanism of action, the drug also inhibits S100A9, a protein involved in differentiation and cell cycle progression. Inhibition of S100A9 also prevents recruitment of myeloid-derived suppressor cells (MDSCs), which are important players in the tumor microenvironment. MDSCs may participate in immune escape and other mechanisms by which tumors evade immunologic attack (Isaacs, 2010). A phase II study of tasquinimod was conducted in men with mCRPC who had not received chemotherapy. The primary end point was radiographic PFS at 6 months. More than 200 men were randomized (2 : 1) to receive tasquinimod or placebo. Median PFS was 7.6 months with tasquinimod versus 3.3 months with placebo ($P = 0.004$). The drug had minimal effects on PSA kinetics, and few men achieved a significant reduction in PSA. Common side effects of tasquinimod were fatigue, nausea, constipation, and anorexia. Grade-3 and higher toxicities included asymptomatic elevations in the lipase and amylase levels, anemia, and venous thrombosis (Pili et al., 2011). Based on these results, tasquinimod advanced to a placebo-controlled randomized phase III trial for patients with similar characteristics to those in the phase II study. Unfortunately, this agent was also unable to improve survival in the pivotal placebo-controlled trial (Sternberg et al., 2016), resulting in cessation of its development in prostate cancer.

c-Met Signaling

The c-Met receptor tyrosine kinase has received considerable attention as a potential therapeutic target for many solid tumors, including prostate cancer. c-Met is the cell surface receptor for the hepatocyte growth factor (HGF). In normal tissues, stromal cells produce HGF, and signaling through c-Met occurs largely via paracrine mechanisms. HGF/c-Met signaling is thought to be important for many physiologic processes, including embryogenesis, organogenesis, angiogenesis, wound healing, and repair of organ damage (Scagliotti et al., 2013; Trusolino et al., 2010). Activation of c-Met can lead to signaling via multiple signal transduction pathways, including Src kinase and the PI3K/Akt/mTOR and MAPK cascades. These pathways activate many cellular processes relevant to cancer, including proliferation, survival, and resistance to apoptosis. HGF/c-Met signaling also promotes invasiveness, motility, and metastasis through changes in the structure of the cytoskeleton and altered integrin expression (Peters and Adjei, 2012).

Abnormal c-Met expression has been observed in a variety of human malignancies, including prostate cancer. Mechanisms responsible for aberrant c-Met signaling include gene amplification and chromosomal rearrangement. Activating mutations and alternative splice variants can also lead to overactive c-Met signaling (Jeffers et al., 1997; Peters and Adjei, 2012; Scagliotti et al., 2013). In prostate cancer, paracrine mechanisms are believed to be predominantly responsible for increased c-Met signaling (Knudsen and Edlund, 2004). High c-Met expression exists in approximately 50% of primary prostate tumors at diagnosis and has been universally observed in bone metastases (Knudsen et al., 2002). In vitro, many CRPC cell lines also express high levels of c-Met mRNA and protein, and they are responsive to HGF in a concentration-dependent manner (Knudsen and Edlund, 2004). Therefore the relationship between AR signaling and c-Met expression has been investigated. To this end, the AR appears to regulate negatively c-Met expression by interfering with Sp1, a transcription factor that binds to the promoter region of the *c-MET* gene. In support of this hypothesis, high c-Met expression has been observed in castration-resistant xenograft models. These findings have led to the conclusion that expression of c-Met and signaling via the HGF/Met axis may be important for the progression of prostate cancer to the castration-resistant state (Verras et al., 2007).

In addition, the presumed importance of c-Met signaling in prostate cancer and its widespread expression in osseous metastases has led investigators to study inhibitors of this signaling pathway in patients with advanced prostate cancer. Although several Met-targeting strategies have been used, cabozantinib (XL184) is the most promising c-Met inhibitor in clinical development for the treatment of prostate cancer. It is an oral tyrosine kinase inhibitor that potently inhibits c-Met and VEGFR2 (as well as RET). In phase I testing, side effects with cabozantinib were manageable and included diarrhea, fatigue, decreased appetite, and rash. The main DLTs of this agent were hand-foot syndrome, mucositis, and elevations of liver enzymes (aspartate aminotransferase [AST] and alanine aminotransferase [ALT]) as well as lipase elevations. Clinical benefit was seen in a broad range of tumor types (Kurzrock et al., 2011).

Based on the responses seen in this phase I study, an international phase II randomized-discontinuation trial was conducted in nine tumor types simultaneously, including a cohort of men with mCRPC. The dose selected for this phase II study was 100 mg daily. All patients received open-label treatment with cabozantinib during a 12-week lead-in stage, and the trial then randomized patients with stable disease at 12 weeks to cabozantinib or placebo. The study oversight committee suspended randomization after the lead-in stage after the accrual of 122 patients, because unprecedented improvements were seen on bone scans across multiple tumor types (including prostate cancer). At that point, median PFS in CRPC patients with cabozantinib was 23.9 weeks compared with 5.9 weeks with placebo (Smith et al., 2013). Ultimately, the study enrolled a total of 171 patients with mCRPC, almost half of whom had previously received chemotherapy. Although the partial radiographic response rate was only 5%, an additional 75% of patients had stable disease. As before, cabozantinib appeared particularly active in treating bone metastases, with 12% of patients showing complete resolution of disease on technetium-99 bone scan. Reductions in pain scores and narcotic use were also observed in a significant proportion of patients. Importantly, PSA changes did not correlate with the favorable results seen on imaging studies or other signs of clinical benefit; some patients exhibited rising PSA levels despite reductions in the size of soft-tissue lesions or bone metastases. The toxicity profile of cabozantinib in this study was similar to that reported in the phase I trial, although higher rates of grade-3 hypertension were seen (Smith et al., 2013).

Cabozantinib was studied in two phase III trials in men with mCRPC with progressive disease after treatment with docetaxel and a novel AR-directed agent (abiraterone or enzalutamide). The first study (COMET-1) evaluated the efficacy of single-agent cabozantinib versus placebo, with a primary end point of overall survival. The second study (COMET-2) investigated the effect of cabozantinib versus mitoxantrone on quality-of-life measures and pain control; the primary end point of that study was the frequency of durable pain responses lasting at least 12 weeks (whereas overall survival was a secondary end point). These trials were considered the registrational studies for cabozantinib in advanced mCRPC. However, both studies failed to meet their primary end points (Smith et al., 2016).

Apoptosis Pathway

Another rational therapeutic approach for multiple cancer types including prostate cancer is the induction of tumor cell apoptosis. To this end, clusterin is a stress-induced antiapoptotic chaperone protein expressed in various cancers including prostate cancer (Zoubeidi et al., 2010), and it has received renewed attention because of the development of an antisense inhibitor to this protein. Importantly, expression of clusterin in prostate tumors increases after treatment with androgen ablation or chemotherapy (July et al., 2002; Miyake et al., 2000), conferring a more resistant phenotype. Custirsen is a novel intravenously administered antisense oligonucleotide moiety that inhibits clusterin at the mRNA level, increasing sensitivity to androgen deprivation as well as chemotherapy in prostate cancer cell lines and in xenograft models (Gleave and Miyake, 2005; Sowery et al., 2008).

In a randomized phase II trial of docetaxel administered with or without custirsen in 82 patients with mCRPC, PSA responses (58% vs. 54%) as well as PFS (7.3 vs. 6.1 months) were similar in both arms. However, there was a trend in overall survival favoring the combination arm (23.8 vs. 16.9 months, $P = 0.06$), although survival was not the primary end point of this study, and confidence intervals around these estimates were wide and potentially confounded by subsequent therapies (Chi et al., 2010). Adverse events associated with custirsen in that trial included fatigue (48%), fever (30% to 50%), rigors (40% to 60%), diarrhea (40% to 60%), and rash (20% to 40%).

Finally, two registrational placebo-controlled phase III trials of custirsen are underway. The first study (SYNERGY) randomized 1022 patients with chemotherapy-naive mCRPC to receive standard docetaxel versus the combination of docetaxel plus open-label custirsen; overall survival was chosen as the primary end point in this trial. This study failed to meet its primary end point (Chi et al., 2017). The second study (AFFINITY) randomized 630 patients with docetaxel-pretreated CRPC to either cabazitaxel alone or cabazitaxel plus custirsen; the primary end point of this study was also overall survival. Unfortunately, that study also failed to achieve its primary end point, calling into question the future development of custirsen in prostate cancer (Beer et al., 2017b).

Targeting DNA Repair

A new class of agents being explored for the treatment of metastatic CRPC are the poly–ADP-ribose polymerase (PARP) inhibitors (Christenson et al., 2018). PARP is an enzyme that is involved in multiple aspects of DNA repair, particularly single-strand DNA repair, and may rescue cells with deficiencies in homologous recombination (which is the primary mechanism of double-strand DNA repair). In several different cancers in which homologous recombination is impaired, pharmacologic inhibition of PARP may result in “synthetic lethality” and apoptosis of cancer cells (Farmer et al., 2005). PARP inhibitors have proven particularly effective in ovarian and breast cancer patients harboring germline and/or somatic mutations in *BRCA1* or *BRCA2* and have already received FDA approvals in advanced breast and ovarian cancers with inherited *BRCA1/2* deficiencies.

Although PARP inhibitors do not appear to be effective in unselected patients with advanced prostate cancer, the drugs may have better activity in tumors harboring somatic and/or germline mutations in DNA repair genes, especially inactivating mutations of homologous recombination genes (e.g., *BRCA1/2, ATM*, *PALB2*, *FANCA* and other Fanconi anemia genes). The prevalence of somatic DNA repair gene mutations in metastatic CRPC appears to as high as 20% to 25% (Robinson et al., 2015). To this end, olaparib (400 mg twice daily) was recently tested in a study of men with heavily pretreated metastatic CRPC (Mateo et al., 2015). Although the response rate to olaparib was only 33% in the unselected population, an 88% response rate was observed in men with germline or somatic mutations in one or more DNA repair genes. In addition, PFS and overall survival were superior with olaparib in the biomarker-positive patients compared with biomarker-negative patients. Based on the results of this study, the FDA has granted olaparib “breakthrough therapy” status for the treatment of metastatic CRPC with germline and/or somatic mutations in *BRCA1/2* or *ATM*. Randomized studies of olaparib versus second-generation hormonal therapy in metastatic CRPC patients with mutated *BRCA1/2* or *ATM* genes (e.g., the PROFOUND trial) are currently underway. A number of other PARP inhibitors are also being tested in advanced prostate cancer, including rucaparib, niraparib, and talazoparib (Christenson et al., 2018). Toxicities of PARP inhibitors include nausea, fatigue, myelosuppression, and a 1% risk of myelodysplastic syndrome or acute myeloid leukemia.

Key Points: Targeted Treatments

- Despite often promising phase II results, phase III trials have failed to demonstrate the clinical utility of angiogenesis inhibition in advanced prostate cancer.
- Because of the reciprocal interactions between the PI3K/Akt/mTOR pathway and AR signaling, dual inhibition of both pathways concurrently will likely represent the most fruitful therapeutic strategy. This is exemplified by the ongoing phase III trial combining the Akt inhibitor, ipatasertib, with abiraterone in mCRPC patients.
- Cabozantinib is a novel small molecule inhibitor of c-Met and VEGFR2 with significant activity on CRPC bone metastases, but it failed to meet its primary end points in the COMET-1 and COMET-2 pivotal trials.
- Custirsen is an antisense oligonucleotide against clusterin mRNA, which may play a role in reversing resistance to taxane chemotherapies, but phase III trials were negative, calling into question its role in the treatment of mCRPC.
- PARP inhibitors (e.g., olaparib, rucaparib, niraparib) are being explored in mCRPC patients with germline or somatic mutations that result in inactivation of homologous recombination DNA repair, which is present in about 20% to 25% of advanced prostate cancers. PARP inhibitors are not currently FDA approved for any prostate cancer indication.

Palliative Management

Pain and Spinal Cord Compression

As in other disseminated malignancies, palliation of symptoms and maintenance of adequate quality of life represent the most important objectives in the management of advanced prostate cancer. Cancer-related pain is undoubtedly the most debilitating symptom associated with advanced-stage metastatic prostatic carcinoma. Prompt recognition of the various pain syndromes associated with this disease is critical to accomplish effective control of this devastating symptom. The most common pain syndromes and their respective therapeutic considerations are summarized in Table 162.1. Focal bone pain in patients with CRPC can be well controlled using external-beam localized radiation therapy. In general, it is also recommended that painful areas that are shown to be abnormal on bone scintigraphy should be evaluated with plain radiographs or CT imaging to exclude the presence of osteolytic lesions or pathological fractures. Such considerations become even more important when the painful areas affect extremities and weight-bearing sites.

TABLE 162.1

Common Pain Syndromes in Metastatic Castration-Resistant Prostate Cancer

PAIN SYNDROME	INITIAL MANAGEMENT	OTHER THERAPEUTIC ALTERNATIVES
Localized bone pain	Pharmacologic pain management	Surgical stabilization of pathological fractures or extensive bone erosions
	Localized radiotherapy (special attention to weight-bearing areas, lytic metastasis, and extremities)	Epidural metastasis and cord compression should be evaluated in all patients with focal back pain
		Radiopharmaceuticals should be considered if local radiation

		therapy fails
Diffuse bone pain	Pharmacologic pain management	Corticosteroids
	“Multispot” or wide-field radiotherapy	Bisphosphonates or RANK ligand inhibitors
	Radiopharmaceuticals	Calcitonin
		Chemotherapy
Epidural metastasis and cord compression	High-dose corticosteroids	Pharmacologic pain management
	Radiation therapy	Physical therapy for recovery of neurologic function
	Surgical decompression and stabilization is indicated in high-grade epidural compressions, extensive bone involvement, or recurrence after irradiation	
Nerve plexopathies caused by direct tumor extension or previous therapy (rare)	Pharmacologic pain management	Tricyclic antidepressants (amitriptyline)
	Radiation therapy (if not previously used)	Anticonvulsants (gabapentin, pregabalin)
	Neurolytic procedures (nerve blocks)	
Miscellaneous neurogenic causes: postherpetic neuralgia, peripheral neuropathies	Complete neurologic evaluation	Tricyclic antidepressants (amitriptyline)
	Pharmacologic pain management	Anticonvulsants (gabapentin, pregabalin)
	Discontinuation of neurotoxic drugs: docetaxel, platinum compounds	
Other uncommon pain syndromes: extensive skull metastasis with cranial nerve/skull base involvement, extensive painful liver metastasis, or pelvic masses	Radiation therapy	Chemotherapy
	Pharmacologic pain management	Intrathecal chemotherapy may ameliorate symptoms of meningeal involvement
	Corticosteroids (cranial nerve involvement)	

RANK, Receptor activator of nuclear factor-κB.

Epidural metastasis is fairly common and is a potentially devastating complication of systemic cancer. In view of the propensity for prostate cancer to metastasize to the vertebrae and paravertebral regions, the incidence of epidural cord compression is particularly high in this disease. Early diagnosis and treatment of epidural metastasis is critical in preserving ambulation and bowel and bladder function and aids in the management of back pain (Gabriel and Schiff, 2004; Grossman and Lossignol, 1990). Epidural cord compressions arising from vertebral bodies account for the majority of spinal cord compressions; less frequently they are associated with soft-tissue masses involving the paravertebral region. Most of these patients have abnormalities on bone scintigraphs and/or abnormal findings on radiography at the time of diagnosis. However, a deficit on neurologic examination may be the only finding in patients who exhibit soft-tissue epidural metastasis in the paravertebral region.

Spinal magnetic resonance imaging (MRI) is used routinely to exclude the possibility of significant epidural disease, and it has almost entirely replaced other methods such as CT myelography and conventional myelography. The first therapeutic intervention in patients with suspected or documented cord compression should include the administration of high doses of intravenous glucocorticoids. Dexamethasone at doses ranging from 16 to 100 mg daily is most commonly used. Patients are often administered an intravenous “loading dose” of 10 mg of dexamethasone followed by 4 to 10 mg every 6 hours; the optimal steroid dose remains relatively undefined. On improvement of symptoms, which can be accomplished promptly with glucocorticoids, the steroid dose may be tapered down throughout a 2-week to 3-week period.

Radiation therapy is often the mainstay of definitive treatment. However, reports suggest that decompressive surgery followed by radiation therapy may be superior to radiation therapy alone (Patchell et al., 2005). To this end, surgery should be considered in patients who have evidence of progressive signs and symptoms during radiation therapy, develop or are seen initially with unstable pathological fractures that require stabilization, or experience recurrence after radiotherapy. In addition, the overall prognosis of the underlying disease should be considered during the treatment selection. Chemotherapy is rarely used to treat epidural cord compression during the acute management of this complication.

Bone-Targeted Approaches

The pathogenesis of bone metastases in prostate cancer remains a subject of major study. Alterations in the normal process of bone absorption and formation, which usually follow an orderly and sequential path, appear to be a key determining factor in the development of bone metastasis associated with most malignant neoplasms (Roodman, 2004). Under normal physiologic conditions the process of bone remodeling is initiated by an increase in osteoclastic activity followed by an increase in osteoblastic differentiation and maturation, which results in the formation of new bone and the repair of the initial absorption caused by osteoblasts. Bone loss associated with prostate cancer can result from an enhanced osteoclastic activity associated with long-term androgen suppression, which in turn can cause excessive resorption of bone mineral and organic matrix. Tumor cells may also cause mineral release and matrix resorption in the areas involved by metastatic disease (Galasko, 1986). In addition, various cytokines, growth factors, tumor necrosis factors, and bone morphogenic proteins have been shown in preclinical studies to play a major role in the induction of osteoclastic and osteoblastic activity (Reddi and Cunningham, 1990). In prostate cancer, bone metastases are predominantly blastic, which reflects a predominance of osteoblastic activity in the process of bone remodeling (Roodman, 2004). This phenomenon may be a result of specific growth factor secretion that is responsible for the induction of osteoblasts. Unlike other bone-tropic malignancies, hypercalcemia is rare in metastatic prostate cancer. In fact, a significantly elevated serum calcium concentration is most frequently a result of the neuroendocrine prostate cancer (see later) and is mediated through parathyroid hormone–related protein (PTHrP) (diSant'Agnese, 1995; Nelson et al., 2007).

Bisphosphonates

Bisphosphonates have become an integral part of the management of metastatic prostate cancer involving the bones (Van den Wyngaert et al., 2009). These compounds reduce bone resorption by inhibiting osteoclastic activity and proliferation. Zoledronate is a potent intravenous bisphosphonate first approved for the treatment of hypercalcemia and decreased bone mineral density in postmenopausal women (Green and Rogers, 2002). In patients with progressive CRPC and bone metastases, zoledronate was shown to reduce the incidence of skeletal-related events (e.g., pain, fractures) compared with placebo in a prospective randomized trial of 422 patients (Saad et al., 2004). In addition, zoledronate and pamidronate have also been shown to increase bone mineral density in patients with nonmetastatic prostate cancer receiving long-term androgen deprivation (Smith et al., 2001, 2003).

At present, zoledronate is indicated for the treatment of patients with progressive CRPC with evidence of bone metastasis, and it is administered at a dose of 4 mg intravenously repeated at intervals of 4 weeks for several months. Side effects of this agent include fatigue, myalgias, fever, anemia, and mild elevation of serum creatinine. Hypocalcemia has been described with the use of zoledronate, and concomitant administration of oral calcium supplements (1000 mg/day) and vitamin D (800 units/day) is often recommended. An unusual complication of zoledronate is the development of severe jaw pain associated with osteonecrosis of the mandibular bone (called osteonecrosis of the jaw [ONJ]). The cause of this phenomenon is not well understood. However, it is most frequently seen in patients undergoing dental work or those with a history of poor dentition and chronic dental disease. Zoledronate should not be administered to patients with these problems. Other bisphosphonates have also been evaluated in prostate cancer, including alendronate, etidronate, ibandronate, and clodronate; however, their benefit has not been conclusively established in prospective randomized clinical trials (Berry et al., 2006; Van den Wyngaert et al., 2009).

RANK Ligand Inhibitors

Interactions between tumor cells and the bone marrow microenvironment have been postulated as an additional important mechanism in the pathogenesis of bone metastasis. Tumor-associated cytokines have been shown to induce the expression of the receptor activator of nuclear factor-κB ligand (RANKL) that binds and activates RANK, which is found in osteoclasts (Brown et al., 2001). Inhibition of the RANKL system has been the focus of much research and represents an evolving bone-targeted strategy. Among the approaches used are monoclonal antibodies to RANKL and the use of recombinant osteoprotegerin (the natural decoy receptor of RANKL), both of which significantly inhibit osteoclastic function in vitro and in vivo (Schwarz and Ritchlin, 2007). Denosumab, a fully human monoclonal antibody against RANKL, was the first agent to enter clinical trials in patients with prostate cancer, as well as breast cancer. In a phase II randomized study evaluating 50 patients with metastatic prostate cancer, denosumab (administered subcutaneously every 4 weeks) produced a reduction in bone resorption beyond that of zoledronate, as indicated by a lowering of urinary *N*-telopeptide levels, and it also resulted in fewer skeletal-related events (Fizazi et al., 2009).

Following from these encouraging results, a pivotal multicenter phase III double-blind randomized study was conducted comparing denosumab against zoledronate for the prevention of skeletal-related events in patients with bisphosphonate-naive mCRPC. In that trial of 1904 patients, compared with men receiving zoledronate ($n = 951$), men receiving denosumab ($n = 950$) showed an improved time-to-first skeletal-related event (20.7 vs. 17.1 months, $P = 0.008$) and a longer time to first-and-subsequent skeletal-related events (HR 0.82, $P = 0.004$) (Fizazi et al., 2011). Notably, there was no difference in overall survival or PFS between study arms. Based partially on the results of this study (and partially on two other large randomized studies in metastatic breast cancer and other solid metastatic tumors), the FDA approved denosumab in November 2010 for the prevention of skeletal-related events in patients with bone metastases from solid tumors. Common toxicities of denosumab include fatigue, nausea, hypophosphatemia, and hypocalcemia (grade ≥3 in 5% of patients). ONJ also occurs in about 2% to 4% of patients, and prophylactic use of calcium and vitamin D supplementation is strongly encouraged. Therefore denosumab is a reasonable alternative to zoledronate for the prevention of skeletal-related events in patients with mCRPC, and it also includes an advantage in that it does not require dose adjustment or monitoring for renal impairment. The recommended dose of denosumab is 120 mg administered by subcutaneous injection every 4 weeks.

Radium-223 and Other Radiopharmaceuticals

The introduction of “bone-seeking” radiopharmaceuticals has provided a useful resource for the management of diffuse bone pain from widespread prostate cancer metastases (Pandit-Taskar et al., 2004), and it may even improve survival (Parker et al., 2013a). Historically the most commonly used compounds were the beta emitters strontium-89 (^{89}Sr) (Porter et al., 1993) and samarium-153 (^{153}Sm) (Sartor et al., 2004), although these agents will largely be replaced by the alpha emitter radium-223 (^{223}Ra). Initial studies with ^{89}Sr showed palliation of bone pain in 25% to 65% of patients with CRPC and diffuse bone pain (Jager et al., 2000). The pharmacokinetics of ^{89}Sr vary considerably according to the extent of bone involvement, but the half-life is generally 4 to 5 days. The retention of this isotope is significantly longer in patients with diffuse osteoblastic metastases compared with those with relatively limited bone involvement. It is important to recognize this factor because it affects the degree and duration of myelotoxicity associated with this radioactive compound (its most significant toxicity). The clinical experience with ^{153}Sm suggests that this isotope is associated with a lower incidence of myelotoxicity, probably because of its shorter half-life of 2 days. Encouraging results were reported by Sartor et al. (2004) in a phase III trial comparing radioactive ^{153}Sm and nonradioactive ^{152}Sm, indicating that a dose of ^{153}Sm of 1 mCi/kg is safe and effective palliation for patients with CRPC and severe bone pain. However, although ^{89}Sr and ^{153}Sm are FDA approved for the palliative management of castration-resistant bone metastases, neither compound was demonstrated to provide a survival advantage. To this end, the novel alpha-emitting agent radium-223 will probably replace these beta emitters because of its capacity not only to palliate bone pain but also to improve overall survival in this setting.

Radium-223 is a novel alpha-emitting radiopharmaceutical that has received significant attention. Alpha particles are approximately 7000 times heavier than beta particles, and as few as one or two hits can be sufficient to cause cell death, in comparison with hundreds or thousands of hits required from beta particles. In addition, alpha particles have a very short path length (<100 μm), which may spare surrounding healthy bone marrow, thereby limiting hematologic toxicities (Henriksen et al., 2003). A series of phase I and II trials demonstrated the safety of radium-223, together with evidence of biologic activity in terms of serum markers of bone turnover and PSA changes, and raised the possibility that treatment with radium-223 may improve overall survival (Nilsson et al., 2005, 2007, 2012; Parker et al., 2013b).

These promising early phase data led to the design of the phase III ALSYMPCA trial (Parker et al., 2013a), as a result of which radium-223 gained FDA approval for use in mCRPC patients with symptomatic bone metastases. This was an international, randomized, double-blind, placebo-controlled phase III study comparing best standard care plus radium-223 versus best standard care plus placebo in men with mCRPC who were chemotherapy-refractory or chemotherapy-ineligible. Enrollment was restricted to men with symptomatic bone metastases in the absence of known visceral disease or bulky lymph-node metastases. Radium-223 was administered at a dose of 50 kBq/kg (intravenously) every 4 weeks for a total of 6 doses. The primary end point of this trial was overall survival, which was improved by radium-223 compared with placebo (HR 0.70, 95% CI 0.58–0.83, $P < 0.001$); this translated into a median survival benefit of 3.6 months beyond placebo (Fig. 162.8; Parker et al., 2013a). In addition, all of the secondary efficacy end points were also met, with a 6-month delay in median time-to-first symptomatic-skeletal event (HR 0.66, 95% CI 0.52–0.83, $P < 0.001$), and a significant improvement in quality of life measured using the FACT-P scale. Remarkably, the incidence of adverse events and serious adverse events was lower in the radium-223 group than in the placebo group. Diarrhea was the most common side effect in ^{223}Ra-treated patients. Hematologic toxicity was rare (e.g., grade 3/4 thrombocytopenia was seen in 6% of men receiving radium-223 vs. 2% for placebo). Based on the results of the ALSYMPCA trial, radium-223 would be a reasonable treatment choice for any patient with symptomatic bone-mCRPC without visceral or bulky nodal metastases. This agent may be used in docetaxel-refractory patients and in those who are ineligible or uninterested in receiving chemotherapy.

Key Points: Palliative Management

- Patients with back pain and a history of bone metastases should be evaluated for spinal cord compression. This clinical syndrome often includes one of the following signs and symptoms: back pain, focal neurologic deficit (motor, sensory), or changes in bladder or bowel control.
- Initial management of suspected cord compression includes immediate MRI of the spine and initiation of high-dose intravenous corticosteroids. Definitive treatment should include radiation therapy, surgical decompression, or both.
- Zoledronic acid and denosumab are both reasonable treatment options for the prevention of skeletal-related events in patients with castration-resistant bone metastases. Denosumab may include the advantage of not requiring renal dosing. Both agents can (rarely) cause ONJ.
- Radium-223 is a novel alpha-emitting radiopharmaceutical that has received FDA approval for the treatment of symptomatic bone metastases in CRPC patients without visceral metastases or bulky lymph node disease.

Neuroendocrine Prostate Cancer

Laboratory and clinical evidence indicate that alterations in the differentiation pathway of prostate cancer can be seen in a small proportion of patients with advanced-stage disease, giving rise to a neuroendocrine/anaplastic transformation (diSant'Agnese, 1995; Nelson et al., 2007). The therapeutic implications of this finding are of significance because tumors demonstrating this phenotype usually represent an inherently endocrine-resistant subtype and, in view of their different clinical and biologic properties compared with the usual adenocarcinoma of the prostate, these tumors also require different treatment strategies.

Such tumors possess a number of biologic characteristics unique to neuroendocrine tumors that can also arise from other organs, most commonly the lung. Among these are the expression of receptors to various neuroendocrine peptide growth factors, such as somatostatin, chromogranin A, and serotonin, as well as PTHrP and *TP53* mutations. These tumors have an uncharacteristic clinical behavior (compared with the usual metastatic prostate cancer), reflected by frequent visceral involvement and rapidly growing soft-tissue metastases. Patients frequently have subacute and often dramatic changes in their disease pattern characterized primarily by a rapidly growing soft-tissue mass (frequently involving the primary site but also with retroperitoneal masses), rapid development of visceral (especially liver) infiltration, osteolytic (as opposed to osteoblastic) bone metastasis, and a high incidence of parenchymal brain involvement (Fig. 162.9). Histologic evaluation is strongly encouraged. This frequently culminates with the demonstration of a small cell variant or a poorly differentiated neoplasm on pathology with the presence of neuroendocrine markers on immunostaining (diSant'Agnese, 1995; Nelson et al., 2007). Interestingly, patients with this tumor phenotype either stop expressing PSA in the presence of major tumor progression or even have undetectable PSA levels at the time of this transformation.

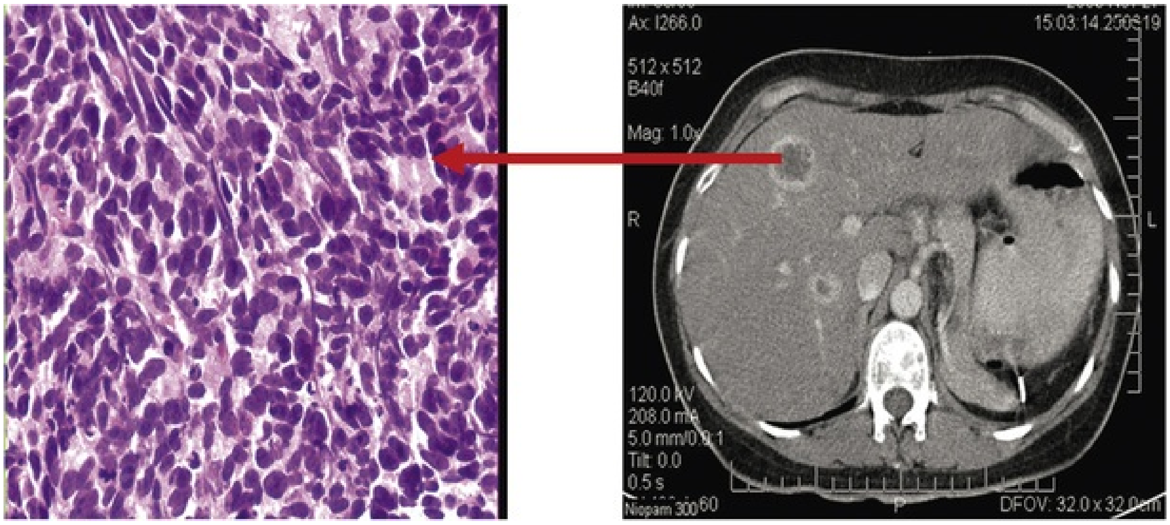

FIG. 162.9 Neuroendocrine/anaplastic carcinoma of the prostate: clinical and pathological features. Red arrow shows histologic section from liver mass biopsy. *PSA,* Prostate-specific antigen.

Treatment of the neuroendocrine/anaplastic phenotype is often similar to that of patients with other neuroendocrine tumors (e.g., small cell carcinoma of the lung) and usually includes combinations of cisplatin and etoposide (Frank et al., 1995), or the combination of a taxane plus carboplatin (Aparicio et al., 2013, 2017) (please also see the section on Platinum agents, earlier). One group has also reported doxorubicin-containing combinations as modestly efficacious (Papandreou et al., 2002). Radiation therapy is effective and should be considered in cases with bulky disease, with brain metastasis, or when local disease control in critical areas may have a positive impact on quality of life (pain, potential pathological fractures, and bladder outlet obstruction). A combined chemotherapy and radiation therapy approach is frequently necessary to accomplish maximal disease control. Despite high initial response rates with chemotherapy and radiation treatment, the prognosis of these patients remains poor and is dependent on various factors, including extent and location of metastases. In general, survival is less than 12 months.

Key Points: Neuroendocrine Prostate Cancer

- Rapidly growing disease with the following clinical characteristics should prompt evaluation for the neuroendocrine subtype: pelvic masses, visceral involvement, osteolytic metastasis with hypercalcemia (associated with high serum PTHrP), and parenchymal brain metastasis.

- PSA is most commonly undetectable (or levels are low/declining) despite evidence of rapid disease progression. Serum chromogranin A and urine serotonin metabolites may be detectable but are not necessary for diagnosis.
- These tumors are invariably unresponsive to hormonal manipulations but are transiently sensitive to radiation therapy and chemotherapy, including platinum-etoposide combinations or platinum-taxane combinations.

Conclusion

With more drugs at our fingertips for the treatment of CRPC than ever before and an increasing number of novel therapeutic targets being discovered every day, we are still left with several challenges and unanswered questions. First we must determine how these approved and experimental therapies should ideally be sequenced in individual patients with CRPC to maximize the therapeutic benefit. Second, we need to develop strategies to combine these drugs optimally in a rational manner, taking advantage of our understanding of negative feedback loops and alternative pathway activation to overcome resistance to monotherapies. Only prospective trials incorporating biomarker-driven hypotheses will ultimately be able to address these key clinical questions. Thus the collection of tumor biopsy specimens or correlative samples may be essential in identifying novel targets or developing enrichment strategies moving forward. Third, we must design smarter trials with the goal of quickly yet reliably identifying agents that do not hold promise, while enabling those that do to move swiftly to registrational studies. Finally we must select our patients more carefully based on clinical or molecular characteristics (e.g., AR-V7, DNA repair mutations) so as to identify the subset most likely to benefit from a particular therapy. Meanwhile several active agents are currently in phase III development, and some of these therapies are also likely to further expand our therapeutic arsenal in the near future for men with mCRPC.

Index

Page numbers followed by “*f*” indicate figures, “*t*” indicate tables, “*b*” indicate boxes, and “*e*” indicate online content.

A

AAST, American Association for Surgery of Trauma

Abdomen

- clinical staging of, TGCTs and, 1689, 1689*f*
- exiting of
  - after laparoscopic and robotic surgery, 218–219
  - complications related to, 230
- hostile, 463

Abdominal aorta, 1669, 1669.e1*f*, 1671*f*, 1672*t*

Abdominal distention, 383, 387*b*

Abdominal incisions, in urologic surgery, 135–136

- Gibson incision, 135–136, 138*f*
- midline incision, 135, 136*f*–137*f*
- Pfannestiel incision, 135, 138*f*

Abdominal leak point pressure (ALPP)

- measurement of, 2561–2562, 2562*f*
- for sling procedure, 2833

Abdominal mesh removal, 2887

Abdominal obesity, 1418–1419

Abdominal paravaginal repair, for pelvic organ prolapse, 2780*t*, 2787, 2788*f*

Abdominal pressure, increased, urinary incontinence during, 2516

Abdominal sacrocolpopexy, for apical pelvic organ prolapse repair, 2798–2809
- complications of, 2804, 2806*t*
- cost of, 2809
- laparoscopic
  - comparison with, 2806, 2807*t*
  - *versus* robotic-assisted, 2806–2809, 2808*t*
  - *versus* robotic-assisted colpopexy, 2809
  - technique for, 2802*f*–2803*f*, 2803–2804
- learning curve in, 2809
- open, technique for, 2798–2800, 2800*f*–2801*f*
- results of, 2804–2806, 2805*t*
- robotic-assisted laparoscopic, 2800–2803, 2801*f*–2803*f*

Abdominal sacrohysteropexy, 2822–2823, 2824*t*

Abdominal surgery, operative team placement for
- retroperitoneal procedures, 207, 207*f*
- transperitoneal procedures, 206, 206*f*, 206.e1*f*
  - complication of, 223*t*

Abdominal testis, surgical management of, 967–968
- Fowler-Stephens orchidopexy, 967–968
- laparoscopic orchidopexy, 967–968
- open transabdominal orchidopexy, 967

Abdominal wall
- closure of, for classic bladder exstrophy, 545–548, 546*f*–548*f*
- defects, in bladder exstrophy, 533
- lower
  - inguinal canal, 2445–2447, 2448*f*
  - internal surface of, 2447–2448, 2448*f*
  - musculature of, 2444–2445, 2447*f*–2448*f*
  - skin and subcutaneous fascia, 2444, 2446*f*
- posterior, 1658–1665
  - flank muscles of, 1658–1665, 1662*f*–1664*f*, 1664*t*
- in prune-belly syndrome, 585–586, 586*f*–587*f*
- reconstruction of, for prune-belly syndrome, 594–595

Abdominal wall defects, 410

Abdominal wall related complications, after robot-assisted cystectomy, 3272

Abdominoperineal resection (APR), LUTD after, 2620–2621

Abdominoscrotal hydroceles, 889, 892–893

Abiraterone, 3677–3678, 3677*f*, 3693–3695, 3694*f*

Ablation

- adjuvants to, 3638
- approach of, 3624
- brachytherapy, 3632–3638
- cryotherapy, 3624–3628, 3625*f*, 3627*t*
- follow up, 3638
- high-intensity focused ultrasonography, 3628, 3629*t*–3630*t*, 3631*f*–3632*f*
- irreversible electroporation, 3628–3632, 3635*f*, 3636*t*
- laser, 3628, 3633*f*, 3634*t*, 3635*f*
- other modalities, 3638
- types, 3624, 3624*f*
- vascular-targeted photodynamic therapy, 3632, 3637*t*

Ablative therapy

- adrenal surgery, 2424–2425
- failure of, laparoscopic radical nephrectomy after, 2298
- laparoscopic ablation *versus*, 2318
- laparoscopic kidney, 2304–2305
- for renal tumors, 2309, 2322
    - new modalities of, 2319–2323, 2323*b*

Abnormal adrenal function disorders, 2383–2384

Absorbable gelatin matrix agents, 147

Absorbable stapling techniques, for cutaneous continent urinary diversion, 3227–3228

- right colon pouch, 3228, 3229*f*
- stapled sigmoid reservoir, 3228, 3230*f*
- W-stapled reservoir, 3228–3229, 3231*f*

Absorbable sutures, 149–150

Absorbed dose, 28

Absorbent products

  - for bladder emptying/storage failure, 2904
  - for urinary incontinence, in geriatric patients, 2920.e6

Absorption, of ultrasound waves, 71, 72*f*

Absorptive hypercalciuria (AH), 2019

ACC, Adrenal cortical carcinoma

Access needles, 169–170, 170*f*

Accreditation, for ultrasonography, 89–90

Acellular human dermis, allograft slings and, 2834–2835

^{11}C-acetate positron emission tomography scan, 3662, 3662*f*

Acetazolamide, in stone formation, 2033

Acetylcholine (ACh)
  - in bladder function, 2474–2475
  - botulinum toxins and, 2512, 2720.e3
  - for detrusor underactivity, 2660–2661
  - mechanism of action of, 2681
  - in ureteral function, 1887

Acid-base balance, filtrate transport, 1911–1912, 1912*f*, 1912*b*

Acid-base metabolic, pneumoperitoneum effects on, 222

Acid-base physiology, 461

Acidosis
  - after augmentation cystoplasty, 698
  - requiring treatment, with intestinal anastomoses, 3180*t*

Acontractile detrusor, 2521, 2565

Acoustical shadow, 71, 71*f*

Acquired curvatures of penis, 1837–1838

Acquired diverticula, 525

Acquired immunodeficiency syndrome (AIDS), lower urinary tract dysfunction and, 2625

Acquired renal cystic diseases (ARCD), 772–774, 774*b*

  - clinical features of, 772
  - etiology of, 772
  - evaluation of, 773
  - histopathology of, 772–773, 773*f*
  - treatment of, 773–774

Acquired renal scars, 499–500

Acquired scarring, pathophysiology of, 500–501, 500*f*–501*f*
  - age, 500
  - bacterial virulence, 500
  - host susceptibility and response, 500
  - hypertension, 501
  - papillary anatomy, 500
  - renal failure and somatic growth, 501
  - renal growth, 501

Acrosome, 1442.e1

ACTH-dependent Cushing syndrome, 2361, 2361*f*
  - Cushing disease, 2361
  - ectopic ACTH syndrome, 2361, 2362*f*, 2362*t*, 2366
  - treatment of, 2365–2366, 2366*f*

ACTH-independent bilateral macronodular adrenal hyperplasia, 2362

ACTH-independent Cushing syndrome, 2362, 2366–2367

Actin, in thin filaments, 2471

Actinomyosin cross-bridge cycling, 2472–2473, 2472*b*, 2473*f*

Action potentials
  - of smooth muscles, of bladder, 2473–2474, 2474*f*
  - of ureteral muscle cells, 1879–1881, 1879*f*–1880*f*

Active surveillance
  - barriers to, of prostate cancer
    - economics, 3546
    - nomenclature, 3546
  - complementary roles of focal therapy and, 3620
  - of prostate cancer, 3537–3547, 3539*b*

        - barriers to, 3545–3546
        - management of men on, 3541–3542
        - outcomes of, 3540–3542, 3540*t*, 3540*b*
        - patient selection in, 3540–3541, 3541*t*
        - research questions in, 3546–3547
        - watchful waiting, 3541
    - for RCC, 2173, 2173*t*

Activin, 1390, 1391*f*

Activities of daily living (ADLs), of geriatric urology patient, 2909

Activity product ratio, 2010

Acupuncture, for PE, 1572.e3

Acute adenolymphangitis (ADL), as filariasis clinical manifestation, 1329

Acute chest syndrome, 451

Acute disseminated encephalomyelitis (ADEM), lower urinary tract dysfunction and, 2625–2626

Acute epididymitis, 1202–1223

Acute focal or multifocal bacterial nephritis, 1171.e1, 1171.e1*f*

Acute interstitial nephritis (AIN), AKI caused by, 1925, 1925*t*

Acute kidney injury (AKI), 1921–1927, 1927*b*
    - in children, 353–354, 353*t*, 353*b*–354*b*
        - prerenal, 353–354
    - definition of, 1921, 1922*t*
    - differential diagnosis of, 1925–1926, 1926*t*
    - epidemiology and classification of, 1922
        - postrenal, 1923
        - prerenal, 1922–1923
    - management of, 1926–1927, 1927*t*
    - staging of, 1922*t*

Acute orchitis, 1218–1219

Acute post-streptococcal glomerulonephritis, 346

Acute pyelonephritis, 1168–1171, 1168*f*–1169*f*, 1170*t*

Acute renal injury, fractional excretion of sodium for, 777

Acute schistosomiasis, 1324

Acute scrotum, 893–899, 893*b*

- epididymitis, 898–899
- MRI, 414
- pain causes of, 899, 899*b*
- spermatic cord torsion, 893–897
- torsion of appendix testis and epididymis, 897–898, 898*f*
- ultrasonography of, 410–411, 411*f*–412*f*, 412*b*

Acute transverse myelitis, lower urinary tract dysfunction with, 2617

Acute tubular necrosis, resulting from ischemic injury, 1923

Acute upper respiratory tract infection (URTI), 450

Acute urinary retention (AUR)

- age and, 3337, 3337*f*
- with benign prostatic hyperplasia, 3336–3339, 3337*f*–3339*f*, 3337*t*–3338*t*, 3400–3401, 3400*t*
- epidemiology
  - of analytical, 3337–3339
  - of descriptive, 3336, 3337*t*
- lower urinary tract symptoms with, 3337–3338, 3338*t*
- management of, 3400–3401, 3401*f*
- prevention with medical therapy, 3401, 3401*b*
- prostate volume in, 3338–3339, 3338*f*–3339*f*
- serum PSA in, 3338–3339, 3338*f*–3339*f*
- urodynamic parameters of, 3338, 3338*f*

AD, Atopic dermatitis

Adalimumab, for BPS/IC oral therapy, 1243

Adaptive immune system, 1334–1336, 1335*f*

ADEM, Acute disseminated encephalomyelitis

Adenine, 1346.e1, 1346.e2*f*

Adenocarcinoma

- of bladder, 3090, 3090*f*
  - in pediatric patients, 1118
- of nonurothelial malignant lesions, 2189

  - of rete testis, 1708
  - of Skene gland, urethral diverticula differentiated from, 2986, 2986*f*

Adenomas
  - as benign lesions, 2362, 2389–2391, 2390*f*, 2391*b*
  - metanephric, 2128–2129, 2129*f*, 2129*b*
  - papillary, of kidney, 2128, 2128*b*
  - prostatic, enucleation of
    - retropubic simple prostatectomy for, 3451–3452, 3451*f*–3452*f*
    - in robot-assisted laparoscopic simple prostatectomy, 3455
    - suprapubic prostatectomy for, 3453, 3453*f*

Adenomatoid tumors, of testicular adnexa, 1709

Adenosine, and ED, 1499

Adenosine triphosphate (ATP), urothelium release of, 2469

Adenylyl cyclase pathway, in ED, 1498

ADHD, Attention-deficit/hyperactivity disorder

Adherence, 428–429

Adhesins, 428–429

Adjuvant androgen deprivation
  - with radiation therapy, for locally advanced prostate cancer, 3653–3654
  - with radical prostatectomy, for locally advanced prostate cancer, 3652

Adjuvant chemotherapy
  - for muscle-invasive bladder cancer, 3120–3125
    - randomized trials of, 3121–3123, 3121*t*
  - for penile cancer, 1798–1800

Adjuvant intravesical topical chemotherapy, after nephroureterectomy, 2220

Adjuvant radiation therapy
  - after radical prostatectomy, for locally advanced prostate cancer, 3650–3652, 3651*t*
  - for biochemical recurrence after radical prostatectomy, salvage radiation therapy *versus*, 3664–3665

Adjuvant therapy, in lymph node metastatic prostate cancer, 3684

Adjuvant topical therapy, for UTUC, 2220

ADL, Acute adenolymphangitis

ADLs, Activities of daily living

ADPKD, Autosomal dominant polycystic kidney disease

Adrenal adenomas
- as benign lesions, 2362, 2393–2394, 2393*f*, 2394*b*
- MRI and, 51–52

Adrenal cancer, in nuclear medicine, 43

Adrenal cortex, physiology of, 2356–2357, 2357*f*, 2357*t*–2358*t*

Adrenal cortical carcinoma (ACC)
- malignant lesions, 2362, 2384–2388, 2384*f*, 2385*t*, 2386*f*, 2386*b*, 2387*t*, 2388*b*
- MRI and, 52
- pediatric, 2388
- surgery, 2408–2409, 2408*b*–2409*b*

Adrenal cyst, as benign lesion, 2393–2394, 2393*f*, 2394*b*

Adrenal disorders, 2354–2404
- of abnormal adrenal function, 2383–2384
- anatomy and, 2355*f*, 2356, 2356*b*
- benign lesions, 2389–2394
  - adenoma, 2362, 2389–2391, 2390*f*, 2391*b*
  - adrenal cyst, 2393–2394, 2393*f*, 2394*b*
  - ganglioneuromas, 2392–2393, 2393*b*
  - myelolipoma, 2392, 2392*f*, 2392*b*
  - oncocytoma, 2391, 2392*b*
  - pheochromocytoma, Pheochromocytoma
- of decreased adrenal function, 2380–2383, 2383*b*
  - clinical characteristics, 2381–2382, 2382*t*
  - diagnostic tests, 2382
  - overview and epidemiology, 2380–2381
  - pathophysiology, 2381, 2381*f*
  - prognosis, 2383
  - treatment, 2382–2383, 2383*t*
- embryology and, 2354–2356, 2356*b*
- histology and, 2355*f*, 2356
- historical background, 2354
- of increased adrenal function, 2360–2380
  - Cushing syndrome, Cushing syndrome
  - pheochromocytoma, Pheochromocytoma

    - primary aldosteronism, Primary aldosteronism
  - malignant lesions, 2384–2388
    - adrenal cortical carcinoma, 2384–2388, 2384*f*, 2385*t*, 2386*f*, 2386*b*, 2387*t*, 2388*b*
    - malignant pheochromocytomas, 2373, 2375, 2389
    - metastases, 2388–2389, 2389*f*, 2390*b*
    - neuroblastoma, Neuroblastoma
    - pheochromocytomas, 2373, 2375, 2389
  - physiology and, 2356–2360, 2360*b*
    - adrenal cortex, 2356–2357, 2357*f*, 2357*t*–2358*t*
    - adrenal medulla, 2358–2360, 2358*f*, 2359*t*–2360*t*

Adrenal glands, 2345–2354, 2346*f*, 2353*b*
  - anatomic relationships in, 2345
  - anatomy, 2355*f*, 2356, 2356*b*, 2405–2406
  - embryology, 2345–2351, 2351*f*, 2354–2356, 2356*b*
  - histology, 2351–2352, 2351*f*, 2355*f*, 2356
  - nerves, 2345, 2350*f*
  - physiology, 2356–2360, 2360*b*
    - adrenal cortex, 2356–2357, 2357*f*, 2357*t*–2358*t*
    - adrenal medulla, 2358–2360, 2358*f*, 2359*t*–2360*t*
  - radiology, 2352–2353, 2352*f*
  - surgical landmarks, 2345, 2347*f*–2348*f*
  - vasculature, 2345, 2348*f*–2349*f*, 2355*f*, 2356, 2405–2406, 2406*f*

Adrenal incidentalomas
  - adrenal surgery for, 2409*b*
  - evaluation of, 2394, 2394*t*

Adrenal lesions, 54, 57*t*

Adrenal magnetic resonance imaging, 51–54

Adrenal medulla, physiology of, 2358–2360, 2358*f*, 2359*t*–2360*t*

Adrenal sex steroid hypersecretion, in evaluation of adrenal masses, 2401–2402

Adrenal surgery, 2405–2426, 2426*b*
  - ablative therapy, 2424–2425
  - complications, 2423–2424, 2423*b*–2424*b*
  - for Conn syndrome, 2409–2410, 2409*b*
  - for Cushing syndrome, 2409*b*, 2410
  - evolution of, 2405

- future of, 2425–2426
- hand-assisted, 2419
- indications, 2403, 2403*f*, 2404*b*, 2406–2407, 2406*f*, 2407*b*
- laparoendoscopic single-site, 2419–2420
- laparoscopic adrenalectomy, 2407–2409, 2407*b*
    - left, 2414–2415, 2415*f*–2416*f*, 2417–2418
    - outcomes, 2421–2423
    - retroperitoneal approach, 2417–2418, 2418*f*, 2422
    - right, 2415–2416, 2417*f*–2418*f*, 2418
    - transperitoneal approach, 2414–2417, 2415*f*–2417*f*, 2422
- natural orifice transluminal endoscopic surgery, 2421
- open adrenalectomy, 2410–2414
    - anterior transabdominal approach, 2412–2413, 2412*f*–2413*f*
    - flank retroperitoneal approach, 2410–2411, 2410*f*–2411*f*
    - left, 2412–2413, 2412*f*–2413*f*
    - outcomes, 2421–2423
    - posterior lumbodorsal approach, 2411–2412, 2411*f*–2412*f*
    - thoracoabdominal approach, 2413–2414, 2413*f*–2414*f*
- partial adrenalectomy, 2421, 2421*b*
- perioperative management for, 2409–2410
- for pheochromocytoma, 2409, 2409*b*
- preoperative and perioperative management for, 2409–2410, 2409*b*
- robot-assisted, 2418–2419, 2419*f*–2420*f*, 2422–2423
- surgical anatomy, 2405–2406, 2406*f*

Adrenal tumors
- ablative therapy for, 2424–2425
- Cushing syndrome and, 2362
- evaluation of, 2394–2403
    - adrenal incidentalomas, 2394, 2394*t*
    - assessment of function, 2399–2403, 2400*b*, 2401*f*, 2402*t*, 2403*b*
    - biopsy, 2398–2399, 2399*f*, 2399*b*
    - imaging, 2394–2398, 2396*f*–2397*f*, 2397*b*
    - size and growth, 2397–2398, 2398*f*, 2398*b*, 2408
    - surgical indications, 2403, 2403*f*, 2404*b*

α-Adrenergic agonists, 1888
- for stress urinary incontinence in women, 2714

β-Adrenergic agonists
- for stress urinary incontinence in women, 2714

  ureteral response to, 1885

Adrenergic agonists, for stress urinary incontinence, 2501

β_3-Adrenergic agonists, for OAB, 2647

α_1-Adrenergic antagonists, for PE, 1572.e1

α-Adrenergic antagonists, 1534

β-Adrenergic antagonists

  to facilitate bladder filling and urine storage, 2682*t*, 2698–2699

    with antimuscarinics, 2706

  for stress urinary incontinence in women, 2714

  ureteral response to, 1888

α-Adrenergic blockers

  and ED, 1506

  for OAB, 2647

α1-Adrenergic blockers

  adverse events with, 3369

  for benign prostatic hyperplasia, 3355–3356

  cardiovascular diseases with, 3369–3370

  classification of, 3356–3357, 3356*t*

  comparison of, 3367–3369, 3368*t*

  complications associated with, 3370–3371

  in elderly, 3370

  hemodynamic side effects of, 3369, 3369*f*

  intraoperative floppy iris syndrome, 3370

  nonselective, 3356

  5α-reductase inhibitors and, 3385, 3386*f*

  safety profile of, 3369

  selective, 3356–3357

  sexual function and, 3370

β-Adrenergic blockers, and ED, 1506

α-Adrenergic receptor antagonists, for bowel-bladder dysfunction, 657–658

Adrenergic receptors

  pharmacology of, 2500–2501, 2501*b*

    - α-adrenergic receptors, 2500–2501, 2501*f*
    - β-adrenergic receptors, 2500
  - in ureteral function, 1888

Adrenogenital syndrome, testicular “tumor” of, 1708

α-Adrenoreceptor antagonists
  - for detrusor underactivity, 2661
  - to facilitate bladder emptying, 2719–2720
  - to facilitate bladder filling and urine storage, 2682*t*, 2697–2698
    - with 5α-Reductase inhibitors, 2707

ADT, Androgen deprivation therapy

Advance TOT sling, 2887–2888

Advanced imaging, for pediatric urology, 390–391
  - computed tomography, 390–391
  - magnetic resonance imaging, 390

Advancement flap, laparoscopic or robotic, 3031, 3032*f*

Advancement procedures, for hypospadias, 918–920
  - M inverted V glansplasty, 920, 922*f*
  - meatal advancement glanuloplasty, 920, 921*f*
  - urethral, 920, 922*f*
  - urethromeatoplasty, 918

AdvaSeal-S, 215.e2

Aerobactin, 429

Aerobic glycolysis, 96

Afferent arterioles, 1869

Afferent neuropeptides, lower urinary tract and, 2501–2502
  - endothelins, 2502
  - prostanoids, 2502
  - tachykinins, 2501–2502, 2501*t*

Afferent pathways
  - in detrusor underactivity, 2653–2655, 2655*f*
  - in lower urinary tract, 2481–2486, 2487*b*
    - cannabinoids, 2486

        - functional properties of, 2482–2483, 2483*f*
        - modulators of, 2483–2484
        - neuromodulation of, 2511
        - nitric oxide in, 2484, 2484*f*
        - pelvic organ interactions with, 2486, 2486*f*
        - properties of, 2481
        - purinergic signaling, 2484–2485, 2485*f*
        - spinal cord pathways of, 2481–2482, 2481*t*, 2482*f*
        - transient receptor potential cation channels, 2485
    - in overactive bladder and detrusor overactivity, 2641–2642
- AFFINITY study, 3702
- AFFIRM study, 3695, 3695*f*
- Aflibercept, 3700
- African plum, for benign prostatic hyperplasia, 3398
- Age
    - acute urinary retention and, 3337, 3337*f*
    - and aging, 2922*b*
        - biology and principles of, 2905–2906
        - demographics of, 2906–2908, 2907*f*–2908*f*
        - detrusor muscle and, 2653, 2654*f*
        - geriatric urology and, 2905–2923
        - lower urinary system and, 2906
        - lower urinary tract dysfunction and, 652, 2509–2510, 2510*b*, 2633
        - orthoptic urinary diversion and, 3237
        - physiologic, 2905–2906
        - prevalence of OAB and, 2639
        - renal calculi and, 2089–2090
        - ureter physiology effects of, 1900, 1901*f*
        - and urinary incontinence, 2582–2583
        - urinary incontinence and
            - conservative interventions for, 2735
        - UTUC variations and, 2185
    - colposuspension and, 2756
    - prostate cancer diagnosis and, 3459
    - renal calculi and, 2006
- Age-based self-assessment pain tools, 448–449, 448*f*
- Agency for Healthcare Research and Quality (AHRQ), 101
- Agenesis, 949

Aging
- hypothalamic-pituitary-gonadal axis and, 1392
- Peyronie's disease and, 1600

β3-Agonist (Mirabegron)
- for benign prostatic hyperplasia, 3381–3393
- indication, efficacy, and safety profile of, 3381–3382

AH, Absorptive hypercalciuria

AHRQ, Agency for Healthcare Research and Quality

AIDS, Acquired immunodeficiency syndrome

AIN, Acute interstitial nephritis

Air-charged catheters, for urodynamic studies, 2558

Air embolism, vena caval thrombectomy causing, 2277

AirSeal System, 211, 211.e3*f*

AKI, Acute kidney injury

Albumin, 1436

Albuminuria
- in CKD, 1928, 1928*t*
- in urine, during pregnancy, 283

Albuterol (Ventolin), for contrast media reaction treatment, 30–31

Alcohol
- consumption, prostate cancer and, 3465
- and ED, 1509
- use, benign prostatic hyperplasia and, 3322

Aldosterone hypersecretion, in evaluation of adrenal masses, 2401, 2401*f*

Aldosterone receptor antagonists, and ED, 1507

Alfuzosin
- for benign prostatic hyperplasia, 3361–3363, 3362*t*
- to facilitate bladder emptying, 2682*t*, 2720.e1

Alfuzosin, Finasteride and Combination study, 3385

Aligning catheters, for PFUIs, 1828

Alkali agents, for pediatric kidney stone disease, 869

Alkalosis, after augmentation cystoplasty, 698.e1

Allantois, 319*f*, 330*f*

Allergic dermatitis

- atopic dermatitis, 1275–1276, 1276*f*
- contact dermatitis, 1276–1277, 1277*f*
- differential diagnosis, 1275*b*
- erythema multiforme and Stevens-Johnson syndrome, 1277–1278, 1278*f*

Allergy

- contrast media and, 32
- patient history of, 8

Allogeneic hematopoietic stem cell transplantation, for RCC, 2331, 2331*t*

Allograft, for pubovaginal sling, 2834–2835

- outcomes of, 2841–2843, 2841*t*–2842*t*

Allopurinol

- for chronic scrotal pain syndrome, 1216
- for pediatric kidney stone disease, 870

Alpha hemolysin, 429

5-Alpha reductase inhibitors, for nocturia, 2674

Alpha/beta ratio, 3593

Alpha-blockers, for chronic scrotal pain syndrome, 1215

Alport syndrome, 347

ALPP, Abdominal leak point pressure

Alprostadil, 1535

ALSYMPCA trial, 3704, 3705*f*

Alternative hormone treatments, in ED, 1530

Alternative therapies, for ED, 1537–1538

Alveolar RMS, 1111, 1112*f*, 1113*b*

Alzheimer disease, and ED, 1502

Amantadine, for delayed ejaculation, 1579

Ambiguous genitalia, 386, 998–1018, 999*f*, 999*b*

Ambulatory urodynamics, 2571–2574, 2574*b*

- clinical utility of, 2571–2574
- monitoring, 484–485

Amebiasis, of genitourinary tract, 1332

American Academy of Pediatrics Guidelines, for febrile urinary tract infection diagnosis and management in young children, 507, 508*t*

American Association for Surgery of Trauma (AAST), Organ Injury Severity Scale for Kidney, 1992*t*

American Joint Committee on Cancer and Union International Control Cancer (AJCC and UICC) staging systems, for penile squamous cell carcinoma, 1748–1750

American Joint Committee on Cancer (AJCC) staging system, for UTUC, 2194, 2195*t*

American Society of Anesthesiologists Classification and Risk, in urologic surgery, 119, 120*t*, 120*b*

American Society of Anesthesiologists Task Force Recommendation, on the prevention of peripheral neuropathies, 146*t*

American Urological Association (AUA)

- best practice statement
    - on antibiotic, prophylaxis, 188
    - on use of VTE prophylaxis, 231
- Guideline for the Surgical Management of Stress Urinary Incontinence, 2875–2876
- RCC management guidelines of, 2162–2163, 2163*f*
- Symptom Score, 109

American Urological Association Symptom Index (AUASI), for benign prostatic hyperplasia, 3344

γ-Aminobutyric acid (GABA), 1494, 1495*t*

- in efferent pathways to bladder, 2488

  - in inhibition of micturition, 2704
- Aminoglutethimide, 3677
- Aminoglycosides
  - prophylaxis with, for uncomplicated urologic procedures, 1194*t*–1196*t*
  - for UTIs, 1150*t*–1153*t*, 1154, 1155*f*
- Aminopenicillins, for UTIs, 1154
- Aminophylline, for ureteral relaxation, 1899
- Amitriptyline (Elavil)
  - for BPS/IC oral therapy, 1241–1242, 1241*t*
  - urethral function effects of, 1903
- Ammonium acid urate stones, 2066
  - in renal calculi, 2032
- Amniotic fluid, 404
  - pulmonary development and, 716–717
- Amoxicillin, for UTIs, 1151*t*–1153*t*, 1154, 1187*t*
- Ampicillin, for UTIs, 1151*t*–1153*t*, 1154, 1170*t*, 1187*t*
- Amplatz dilators, 171, 171*f*
- Amplitude-coded color Doppler sonography, 389
- Ampulla, 335
- Amputation
  - penile, traumatic, 3050–3051
  - of penis, for penile cancer, 1752–1753
- Amyloidosis
  - lower urinary tract dysfunction and, 2632
  - of urethra, reconstructive surgery for, 1810
- Anaerobes, in urinary tract, 1133
- Anal perineum, female, 2435, 2436*f*
- Anal sphincter, 2435
- Anal triangle

- female, 2434
- male, 2449–2450

Analgesia
- for pediatric patients, 447*b*
  - children of Jehovah's Witnesses, 448
  - children with asthma, 447–448
  - children with spina bifida, 452
- for prostate biopsy, 3496–3497

Analgesics, UTUC risk and, 2187

Anaplastic Wilms tumor, 1100

Anastomosis, excision and primary, for transmen, 3071

Ancillary procedures, in pediatric kidney stone disease, 861

Androgen, 1390
- for benign prostatic hyperplasia, manipulation of, 3371–3379
  - aromatase inhibitors for, 3377
  - cetrorelix, 3377
  - chlormadinone acetate, 3377
  - dutasteride, 3374–3376, 3374*f*, 3375*t*, 3376*f*
  - finasteride, 3371–3374, 3373*t*
  - flutamide, 3376–3377
  - literature interpretation for, 3371
  - literature review for, 3371
  - pharmacological classification for, 3371, 3372*t*
  - rationale for, 3371
  - 5α-reductase inhibitors and sexual dysfunction, 3378
  - selective estrogen and androgen receptor modulators, 3377
  - summary for, 3379
  - tolerability and safety of, 3378
  - zanoterone, 3376
- lower urinary tract and, 2503
- in nuclear matrix, 3294–3295
- plasma binding proteins of, 3282*f*, 3284
- in prostate cancer, 3462, 3466, 3467*f*
- in prostate growth, 3282–3283, 3283*f*
  - metabolism of, 3286–3287, 3286*f*, 3287*t*
  - regulation of, 3285–3286, 3285*f*
- role in benign prostatic hyperplasia, 3306–3308, 3306*t*
- sources of, 3673, 3674*t*, 3674*b*

- stromal-epithelial interaction regulation by, 3287
- synthesis inhibition, 3677–3678

Androgen axis
- androgen sources in, 3673, 3674*t*, 3674*b*
- blockade mechanisms for, 3673–3678, 3679*b*
  - response to, 3679–3680
- molecular biology of, 3672–3673, 3672*f*, 3673*t*, 3673*b*

Androgen-binding protein, 1396–1398

Androgen deprivation therapy (ADT), 3687
- for biochemical recurrence after radiation therapy, 3668–3670
- for biochemical recurrence after radical prostatectomy, 3665
  - salvage radiation therapy with, 3663–3664
- continuous, 3683–3684
- intermittent *versus* continuous, 3684–3685
- for localized prostate cancer, immediate *versus* delayed, 3684
- for locally advanced prostate cancer, 3655–3656, 3656*b*
  - intermittent, 3656
  - quality of life, 3656

Androgen receptor (AR), 3293*b*
- in benign prostatic hyperplasia, 3307
- chaperonin binding, 3289
- defects of, 1013–1014
- dimerization of, 3291
- DNA-binding domain, 3289–3290
- function of, 3295*b*
- ligand-binding domain, 3290–3291
- modulation of, for castration-resistant prostate cancer, 3695–3696, 3695*f*
- nuclear localization of, 3291
- post-translational modifications of, 3291
- in prostate cancer, 3472
- in prostate growth regulation, 3288–3292, 3289*f*–3290*f*
- structure of, 3295*b*
- transcriptional activation domains, 3291–3292, 3291*b*, 3292*f*

Androgen receptor-associated biomarkers, 3685–3686

Androgen receptor-dependent chromatin remodeling, in prostate growth regulation, 3293–3295

Androgen receptor splice variant 7 (AR-V7), 3696

Androgen receptor splice variants, 3685

Androgen suppression, combined with radiation, 3600–3602, 3602*b*
- background and potential mechanisms of, 3600
- localized disease and, 3600–3602, 3601*t*
- locally advanced disease and, 3602
  - benefit of, 3602
- optimal duration of, 3602

Andropause, 1392

Androstenedione, 3283, 3283*f*

Anejaculation, 1451
- causes of, 1574, 1574*t*
- and neurologic disorders, 1576–1577
- treatment of, 1578–1579, 1579*t*

Anemia
- in CKD, 355
- hormonal therapy and, 3682

Anesthesia
- acute perioperative events, 452–453
  - nonspecific fever, 453
  - sepsis, 452, 453*b*
  - trauma, 452–453
  - URTIs, 453
  - UTI, 453
- children with asthma, 447–448
- comorbidities, 450–453
- disposal of unused narcotics, 456, 457*t*
- ERAS protocols, 453–455
- in geriatric urology patient, 2912
- intraoperative considerations, 453–454
  - anaphylaxis, 454–455
  - fluid management, 454

    - malignant hyperthermia, 454–455
    - pain management, 455
    - preoperative antibiotics, 453–454, 454*t*
- for laparoscopic and robotic surgery, complications related, 228
- for laparoscopic kidney surgery, 2279
- laparoscopic procedures, 455–456
- for laparoscopic radical prostatectomy, 3568–3570
- for pediatric kidney stone disease, 861
- for pediatric patients, 447, 447*b*
- for percutaneous nephrolithotomy, 2104
- perioperative home, 447, 457*b*
- perioperative planning and postoperative considerations, 450–453, 452*b*
    - acute upper respiratory tract infection (URTI), 450
    - anaphylaxis, 454–455, 455*b*
    - for asthma and pulmonary disease, 450
    - for cardiovascular anomalies, 450–451
    - chemotherapy and, 451
    - congenital adrenal hyperplasia, 452
    - fluid management, 454
    - hematologic disorders, 451
    - oncologic disorders, 451–452
    - pheochromocytoma, 451–452
    - for premature infants, 450
    - for renal abnormalities, 451
    - spina bifida, 452
- post care unit and pain management, 456
- postoperative management, 455–456
    - immediate, 455–456
    - inpatient, 456
    - outpatient, 456
- and potential neurocognitive effects, 447
- preoperative assessment
    - department of social services, 448
    - diabetes and metabolic disorders, 449–450
    - enteral tube feeds, 449
    - fasting times, 449
    - for Jehovah's witness, 448
    - ketogenic diet, 449
    - medication administration, 450
    - NPO status, 449, 449*t*
    - pain assessment tools, 448–449

- risk, 447–448
- setting, 448
- special, 448
- preoperative studies, 450
  - chest X-ray, 450
  - laboratory tests, 450
  - pulmonary function testing, 450
  - urine evaluation, 450
- preparation for surgery, risk, 447–448
- pubovaginal sling procedure, 2836–2837
- for retropubic radical prostatectomy, 3551–3552, 3551*f*
- for simple prostatectomy, 3450
- for vasectomy, 1850

Aneurysm
- as laparoscopic and robotic surgery contraindication, 204
- in penile implant, 1593, 1593*f*

Angioembolization
- indications for, 1072–1073
- of isolated renal segment, 1072
- for renal injuries, 1986, 1986*f*

Angiogenesis
- in castration-resistant prostate cancer, 3700–3701
- in RCC, 2146
- in UTUC, 2197

Angiography
- in adrenal radiology, 2353
- interventional, for priapism, 1560–1561, 1561*f*
- of renal artery, 179*f*
- renovascular hypertension, screening tests for, MRA, 1917–1918, 1918*b*
- for renovascular hypertension screening, 1917–1918, 1918*b*

Angiokeratomas of Fordyce, 1302, 1303*f*

Angiomyolipoma (AML), 293
- in pediatric patients, 1110, 1110*f*
- renal, 2125–2128, 2128*b*
  - diagnosis of, 2125–2126, 2126*f*

        - epidemiology of, 2125
        - management of, 2126–2128, 2127*f*
        - pathophysiology of, 2125

Angiotensin, urethral function effects of, 1902

Angiotensin II (AT2)
- renal vascular tone control by, 1913
- in tubulointerstitial fibrosis, 788
- type 1 receptor antagonists, and ED, 1507

Angiotensin receptor blockers (ARBs), AKI caused by, 1922

Angiotensin-converting enzyme (ACE), 788

Angiotensin-converting enzyme (ACE) inhibitors
- AKI caused by, 1922
- and ED, 1506–1507

Anhydrous ethanol, for prostatic injections, 3447

Animal bites, of penis, 3050

Animal models, laparoscopic training with, 232

Animal protein
- in pediatric kidney stone disease, 869
- for urinary lithiasis, 2047–2048, 2048*b*

Annexin A3, as prostate cancer biomarker, 3487

Anogenital distance, 305

Anorectal defects
- in bladder exstrophy, 533
- urinary fistula with, 622–623, 622*f*

Anorectal malformation, 386, 644–645, 650*b*
- pathogenesis of, 645
- presentation of, 644–645, 646*f*
- specific recommendations for, 645

Anorgasmia, patient history of, 6

ANP, Atrial natriuretic peptide

Antegrade endoscopic evaluation, for UTUC, 2191

Antegrade injection, of male stress urinary incontinence, 2896–2897

Antegrade nephroureteroscopy, for UTUC, 2212–2219

- biopsy and definitive therapy in, 2216–2217, 2216*f*–2217*f*
- consideration for urinary diversions, 2219
- establishment of nephrostomy tract, 2215–2216, 2215*f*
- result of, 2217–2219, 2218*t*
- second-look nephroscopy in, 2217

Antegrade pyelography

- for genitourinary tuberculosis diagnosis, 1312–1313
- for ureterovaginal fistula, 2943
- for urinary tract obstruction, 781

Antegrade ureterography, of ureteral injuries, 1995

Antenatal urinary incontinence, 2726

Anterior approaches, for open kidney surgery, 2252–2253

- chevron incision, 2253
- midline, 2252–2253, 2253.e1*f*
- subcostal, 2253

Anterior colporrhaphy, for pelvic organ prolapse

- complications of, 2782–2783
- results with, 2779–2782, 2780*t*
- technique for, 2779, 2779*f*

Anterior compartment prolapse, 2587

Anterior cutaneous perforating nerves, 136*f*

Anterior extraperitoneal approach, to laparoscopic pyeloplasty, 1956

Anterior labial commissure, 1627.e1

Anterior pituitary, in HPG axis, 1390–1391, 1391*f*

Anterior-posterior renal pelvic diameter, in perinatal urology, 359–360, 360*t*

Anterior transabdominal approach, to open adrenalectomy, 2412–2413, 2412*f*–2413*f*

Anterior trunk, 2451*t*, 2452

Antiandrogens, 3674–3676, 3675*f*

- and ED, 1508, 1509*t*
- nonsteroidal, 3674–3676
- for priapism, 1553
- steroidal, 3674
- withdrawal syndrome, 3676

Antibiotic prophylaxis, in urologic surgery, 127–128, 127*b*

Antibiotic Prophylaxis and Recurrent Urinary Tract Infection in Children (PRIVENT) study, 516

Antibiotics

- for BPS/IC oral therapy, 1243
- for hypospadias, preoperative, 916–918
- for inguinal lymphadenectomy, 1801
- before inguinal node dissection, 1800–1801
- pediatric stone disease and, 867
- for percutaneous nephrolithotomy, 2104
- prophylaxis with, for cystourethroscopy, 188, 189*t*
- for prostate biopsy, 3496, 3496*t*
- for renal calculi, pretreatment, 2071
- urethral function effects of, 1904
- for vesicovaginal fistula surgery, 2934

Anticholinergic medication

- detrusor underactivity and, 2657
- for urinary incontinence, in geriatric patients, 2919.e1

Anticholinergic receptor blockers, for benign prostatic hyperplasia, 3389–3393, 3390*t*, 3392*f*

Anticholinergics, Antimuscarinic agents

- for bowel-bladder dysfunction, 657
- for enuresis, 665

Anticholinesterases, ureteral response to, 1887–1888

Anticoagulants, for vena caval thrombectomy, 2266–2267

Anticoagulated patient
  holmium laser enucleation of prostate and, 3438
  monopolar transurethral resection of prostate in, 3416
  photoselective vaporization of prostate and, 3441
Anticoagulation
  for inguinal lymphadenectomy, 1801
  before inguinal node dissection, 1801
Anticonvulsants, and ED, 1508
Antidepressants
  and ED, 1507–1508
  to facilitate bladder filling and urine storage, 2682*t*, 2702–2703
Antiglomerular basement membrane (Anti-GBM) disease, 347
Antihistamines
  for BPS/IC oral therapy, 1242
  for contrast media reaction treatment, 31
Antihypertensive agents
  and ED, 1506–1507, 1509*t*
  effect on sexual function, 1507*t*
Antihypertensive and Lipid-Lowering Treatment to Prevent Heart Attack Trial (ALLHAT), 3369–3370
Anti-inflammatory therapy, for chronic scrotal pain syndrome, 1215
Antimicrobial formulary, for UTIs, 1150–1155, 1150*t*–1151*t*, 1155*f*
Antimicrobial prophylaxis
  for common urologic procedures, 1193–1201, 1193*b*, 1194*t*–1196*t*, 1201*t*, 1201*b*
    for lower tract endoscopy, 1198
    for open and laparoscopic surgery, 1199–1200
    principles of, 1193–1197, 1193*b*, 1194*t*–1196*t*
    for shock wave lithotripsy, 1198
    special considerations, 1200–1201, 1201*t*
    for transurethral resection of prostate and bladder, 1198–1199
    for TRUSP biopsy, 1197–1198
    for upper tract endoscopy, 1199
    for urethral catheterization and removal, 1193*b*, 1194*t*–1196*t*, 1197
    for urodynamics, 1197

for UTIs, 1130, 1162–1163

Antimicrobial selection, for uncomplicated cystitis, 1156–1157

Antimicrobial suppression, for UTIs, 1130

Antimicrobial therapy, for UTIs

- antimicrobial formulary for, 1150–1155, 1150*t*–1153*t*, 1155*f*
- bacterial resistance to, 1144–1146, 1145*t*–1146*t*, 1147*b*
- duration of, 1155
- principles of, 1149–1155, 1155*f*, 1155*b*
- prophylaxis, 1130
- selection of agents in, 1155–1157
- suppression, 1130

Antimuscarinic agents

- adverse effects of, 2683–2684
- clinical use of, 2683
- to facilitate bladder filling and urine storage, 2681–2684, 2682*t*, 2697*b*
  - with 5α-reductase inhibitors, 2707
  - with α-adrenoreceptor antagonists, 2704–2706
  - atropine sulfate, 2684
  - with β_3-adrenoreceptor agonist, 2706
  - combinations of, 2706–2707
  - darifenacin hydrobromide, 2684–2685
  - fesoterodine fumarate, 2685–2687
  - flavoxate hydrochloride, 2696
  - imidafenacin, 2687
  - oxybutynin chloride, 2693
  - propantheline bromide, 2688
  - propiverine hydrochloride, 2695–2696
  - solifenacin succinate, 2688–2689
  - tolterodine tartrate, 2689–2691
  - trospium chloride, 2691–2692
- mechanism of action of, 2681–2682, 2681*f*
- for neuromuscular dysfunction of lower urinary tract, 633–634
- nocturnal polyuria and, 2668–2669
- pharmacologic properties of, 2682–2683
- for urinary incontinence
  - in geriatric patients, 2920.e3
  - urgency, 2544

Anti-neutrophil cytoplasmic antibodies (ANCA)-associated glomerulonephritis, 347

Antioxidant therapy, for calcium oxalate precipitation, 2020

Anti-PD-1 approved therapies, 2223

Anti-PD-L1 approved therapies, 2223–2224

Antiproliferative factor (APF), in BPS/IC etiology, 1232.e7, 1232.e8*b*

Antipsychotics, and ED, 1507

Antireflux procedure
- for classic bladder exstrophy, 554–556, 555*f*–556*f*
- for urinary tract reconstruction, 683–685, 685*b*
  - with intestinal segments, 683–685
  - psoas hitch for, 683, 684*f*
  - single ureteral reimplant for, 683
  - transureteroureterostomy for, 683, 683*f*

Antiretroviral agents
- and ED, 1509
- in stone formation, 2032–2033

Antiseptics, for cystourethroscopy, 189

Antisperm antibodies, 1398–1399

Antithrombotic therapy, in urologic surgery, 32–34, 57*t*

Antituberculosis drugs, 1311*t*, 1315–1317, 1315*t*–1316*t*

Anuria, 386, 461

Anxiety
- contrast media and, 32
- prostatitis and, 1210

Anxiolytics, and ED, 1508

Aorta, 1669, 1669.e1*f*, 1671*f*, 1672*t*
- in radical nephrectomy, 2258, 2258*f*, 2258.e1*f*
- reconstruction of, RPLND with, 1719

Aortic aneurysm, as laparoscopic and robotic surgery contraindication, 204

Aortic replacement, in retroperitoneal tumors, 2243

Apalutamide, 3676, 3695–3696

Aphallia, 876–877, 877*f*

Aphthous ulcers, 1286–1287, 1287*f*

Apical mesh complications, 2886–2887

Apical prolapse, 2587

Apoptosis
- after renal obstruction, 790
- as evolutionarily conserved process, 1365–1366
- in GU cancers, 1365–1367, 1367*b*
  - alternative regulators of, 1366–1367
  - extrinsic pathway, 1366.e1*f*–1366.e2*f*, 1366.e2
  - global defects in, 1366–1367
  - intrinsic pathway, 1366.e1, 1366.e1*f*
  - TP53 role in, 1366
- pathway, in castration-resistant prostate cancer, 3701–3702
- regulation of, 783–784
  - in benign prostatic hyperplasia, 3309
- in UTUC, 2197

Apparent diffusion coefficient maps, 63–64, 64*f*

Appendicovesicostomy, 708, 708*f*

Appendix
- for continent urinary diversions, 707–708
- in ileocecocystoplasty, 694

Appendix epididymis, 319*f*

Appendix testis, 319*f*

APR, Abdominoperineal resection

Aprepitant, to facilitate bladder filling and urine storage, 2713.e4

Aquaporin 2 (AQP2), 793

Aquaporins (AQPs), 793

AR, Androgen receptor

ARBs, Angiotensin receptor blockers

ARCD, Acquired renal cystic diseases

Arcuate arteries, 1869

Arcus tendineus fascia pelvis (ATFP), 2427, 2429*f*, 2438

Arcus tendineus levator ani (ATLA), 2427, 2429*f*

Area under the curve (AUC), 3479

Areflexia, 2565

- in detrusor underactivity, 2650

L-Arginine

- for BPS/IC oral therapy, 1241*t*, 1243
- for female sexual arousal disorders, 1650

Arginine vasopressin (AVP), in water regulation, 2668, 2670*f*

Argon beam coagulator

- for laparoscopic and robotic surgery, 215.e1
- for monopolar electrosurgery, 235

Aristolochic acid nephropathy, in UTUC, 2187

Aromatase inhibitors, for benign prostatic hyperplasia, 3377

Arousal, female sexual dysfunction and, 1637

ARPKD, Autosomal recessive polycystic kidney disease

Arsenic, UTUC risk and, 2187

Arterial revascularization, in ED, 1537

Arterial supply, to male pelvis, 2451–2452, 2451*t*

Arterial system, 1807.e9

- of retroperitoneum, 1669–1672, 1669.e1*f*–1669.e2*f*, 1671*f*, 1671.e1*f*, 1672*t*

Arterial system, surgical anatomy of, 3548, 3549*f*

Arterioureteral fistulas, 1993

Arteriovenous fistulas (AVFs), renal, 737

Artifacts, of ultrasonography images, 71–73, 72*f*–73*f*

Artificial somatic-autonomic reflex pathway procedure, for neuromuscular dysfunction of lower urinary tract, 638

Artificial urinary sphincter (AUS), 2546–2547

- for bladder neck reconstruction, 687–688
    - results with, 687–688
    - technique for, 687.e1
- complications with, 3005–3008, 3008*b*
    - mechanical failure, 3007
    - sling, 3008
    - special circumstances of, 3007–3008
    - urethral atrophy, 3007
    - urethral erosion, 3006–3007
    - urinary retention, 3005
- evaluation of persistent incontinence after, 2997–2998
- history and development of, 2994, 2994*f*
- implantation technique, 3000, 3001*f*, 3003*f*
    - bladder neck, 3003–3004, 3005*b*
    - control pump placement, 3000, 3002*f*
    - making connections, 3000, 3002*f*
    - outcomes of, 3003*t*
    - pressure-regulating balloon, 3000
    - tandem cuff, 3000–3002, 3003*f*
    - transcorporal, 3002, 3004*f*
    - trans-scrotal, 3002–3003, 3003*f*
- infection, 3005–3006
- long-term results with, 3008, 3009*b*
- for neuromuscular dysfunction of lower urinary tract, 637

AR-V7, Androgen receptor splice variant 7

As low as reasonably achievable (ALARA) principle, 78, 403, 403*b*

ASB, Asymptomatic bacteriuria

Ascending route of infection, 1131

Ascent anomaly, 339, 339*f*

Ascites

- laparoscopic and robotic surgery causing, 231.e1
- as laparoscopic and robotic surgery contraindication, 204

Ask-Upmark kidney, 744, 744*f*

Aspiration
  of gastric contents, during laparoscopic and robotic surgery, 228.e1
  of testis, technique of, 1847–1848
Assisted reproduction, 1445–1452, 1445.e3, 1445.e3*t*
Asthma
  contrast media and, 32
  preoperative care for pediatric patients with, 447–448
Asymmetrical unit membrane (AUM), of urothelium of bladder, 2462, 2463*f*
Asymptomatic bacteriuria (ASB), 434–435
  in elderly, 1147–1149, 1147*t*
  in geriatric patients, 2920.e10–2920.e11
  in pregnancy, 1185
Atamestane, for benign prostatic hyperplasia, 3377
ATFP, Arcus tendineus fascia pelvis
Atherosclerotic renal artery stenosis, 1930–1933
  arterial physiology, concepts in, 1930–1931, 1930*f*–1931*f*
  clinical features of, 1931–1932
  diagnostic evaluation of, 1931–1932
  hypertension in, pathophysiology of, 1930–1931
  ischemic nephropathy, pathophysiology of, 1931
  laboratory features of, 1932
  radiographic assessment of, 1932–1933
  therapeutic options for, 1933
    medical management, 1933
    procedural management, 1933
ATLA, Arcus tendineus levator ani
Atopic dermatitis (AD), 1275–1276, 1276*f*
ATP, Adenosine triphosphate
Atrial natriuretic peptide (ANP)
  in bilateral ureteral obstruction, 791–792
  renal vascular tone control by, 1913, 1913*f*

Atropine, ureteral response to, 1888

Atropine sulfate, to facilitate bladder filling and urine storage, 2682*t*, 2684

Attention Deficit Hyperactivity Disorder scale, 477

Attention-deficit/hyperactivity disorder (ADHD)

- lower urinary tract dysfunction and, 2633
- and priapism, 1545

Attenuation mechanisms, in ultrasonography, 71, 71*f*–72*f*

Attribution bias, 103–104

“Atypical suspicious for carcinoma,”, 3506

AUA, American Urological Association

AUASI, American Urological Association Symptom Index

AUC, Area under the curve

Audiovisual and vibratory stimulation, in ED, 1526

Augmentation cystoplasty, 2889–2890

- approach to, 701
- bladder capacity after, 2889–2890
- bladder compliance after, 697–698, 697*f*, 2889
- bladder level after, 2889–2890, 2890*b*
- capacity of, 2889
- cecocystoplasty for, 694
- complications of, 635–636, 696–701
    - calculi, 699
    - delayed spontaneous bladder perforation, 700–701, 700*f*
    - metabolic, 698
    - mucus, 698
    - urinary tract infection, 699
- contraindications to, 2890
- detrusor overactivity and, 2889–2890
- gastrocystoplasty for, 695
- gastrointestinal effects of, 696–697
- historical perspective on, 2889
- ileocecocystoplasty for, 694, 694*f*–695*f*

ileocystoplasty for, 692–693, 693*f*

ileovesicostomy for, 702, 702*b*

indications for, 2889–2890

intestinal segment management for, 692

native bladder management for, 692, 692*f*

necessity of, 701–702

for neuromuscular dysfunction of lower urinary tract, 635–636

postoperative management of, 695–696

early, 695

late, 696

pregnancy and, 701

quality of life and, 702

in renal transplantation, 1058

results with, 696–701

segment choice for, 701

sigmoid cystoplasty for, 694–695, 696*f*

techniques for, 2890

for urinary tract reconstruction, in pediatric patients, 691–706, 702*b*

Augmented anastomosis, for urethral stricture disease, 1821–1823, 1826*f*–1827*f*

Augmented bladders

renal transplantation and, 1057–1058

tumors of, in pediatric patients, 1118

Augmented valved rectum, 3209

AUM, Asymmetrical unit membrane

AUR, Acute urinary retention

AUS, Artificial urinary sphincter

Autoaugmentation

for augmentation cystoplasty, 703–705, 704*f*

for neuromuscular dysfunction of lower urinary tract, 636

Autoimmunity, BPS/IC etiology and, 1232.e2–1232.e3, 1232.e3*b*

Autologous graft, for pubovaginal sling, 2834

outcomes of, 2839–2841, 2840*t*

Autonomic dysreflexia
- lower urinary tract dysfunction with, 2614–2615
- symptoms of, 2614
- treatment of, 2614–2615

Autonomic nervous system
- and ED, 1527
- in retroperitoneum, 1674–1675, 1676*f*–1677*f*

Autonomic pathways, penile erection and, 1490, 1490*f*

Autonomy, definition of, 115

Autosomal dominant polycystic kidney disease (ADPKD), 349–350, 405, 750–755, 755*b*
- clinical features of, 752
- emerging therapeutics for, 755
- evaluation of, 753–754, 753*f*–754*f*
- extrarenal manifestations of, 752–753
- genetics of, 750–751
- histopathology of, 753, 753*f*
- pathogenesis of, 751–752
- prognosis of, 754–755
- renal cell carcinoma association with, 753
- renal cell carcinoma in, 2158
- treatment of, 754–755

Autosomal recessive polycystic kidney disease (ARPKD), 349, 405, 746–749, 751*b*
- clinical features of, 748
- evaluation of, 748–749, 749*f*–750*f*
- genetics of, 748
- histopathology of, 748, 748*f*
- treatment of, 749

Autotransplantation
- ureteral injuries, upper, 1997
- for ureteral stricture disease, 1975

AVFs, Arteriovenous fistulas

Avitene Microfibrillar Collagen Hemostat, 215.e2

AVP, Arginine vasopressin

Avulsion

- injury, ureteral, with ureteroscopy, 2002
- in ureteroscopic stone management, 2109

Axial flaps, for urethral and penile reconstruction, 1807, 1807*f*–1808*f*

Axial resolution, of ultrasonography images, 70, 70*f*

Axitinib, for RCC, 2179*t*–2180*t*, 2336–2337, 2337*t*

Azathioprine derivatives, for BPS/IC oral therapy, 1241*t*, 1243

Azoospermia, 1445.e1

Azotemia, with benign prostatic hyperplasia, 3336

Aztreonam, for UTIs, 1151*t*–1153*t*, 1154–1155

B

Bacille Calmette-Guérin (BCG)

- in bladder cancer, 1333, 1334*f*, 1338–1339, 1339*f*
- for non-muscle-invasive bladder cancer, 3099–3100
    - carcinoma treatment in situ with, 3100
    - contraindications to, 3102*b*
    - mechanism of action of, 3100
    - prophylaxis to prevent recurrence, 3100–3101
    - residual tumor treatment, 3100
    - toxicity management of, 3102*b*

Baclofen

- drug delivery of, 2720.e2
- to facilitate bladder emptying, 2720.e2–2720.e3
- to facilitate bladder filling and urine storage, 2682*t*, 2704
- for priapism, 1553–1554

Bacteremia, 427, 428*f*

- UTIs and, 1182–1187, 1184*b*

Bacteria

- cell wall components, in septic shock, 1183
- mesh complication with, 2878
- urease production by, 2030–2031, 2031*t*
- in urine, 23, 24*f*
- urothelial cancer and, 3099

Bacterial adherence, 1134–1135

Bacterial adhesins, 1134

Bacterial fimbriae, 428–429

Bacterial nephritis, 435, 435*f*

Bacterial persistence, in recurrent UTIs, 1160–1161

Bacterial “relapse,” renal infection from, 1177.e1

Bacterial resistance, to UTI antimicrobial therapy, 1144–1146, 1145*t*–1146*t*, 1147*b*

Bacterial type 1 (mannose-sensitive) pili, 1134

Bacterial vaginosis, 1271–1272, 1272*t*

Bacteriology, sepsis and, 1184

Bacteriuria
- after augmentation cystoplasty, 699
- catheter-associated, 1190, 1191*b*
- in elderly, 1188–1190, 1190*b*
  - asymptomatic, 1147–1149, 1147*t*, 1147*b*–1149*b*
  - diagnosis, 1188–1189
  - epidemiology, 1188
  - management, 1189–1190, 1189*t*
  - pathogenesis, 1188
  - screening for, 1188
- in pregnancy, 1184–1185, 1188*b*
  - anatomic and physiologic changes and, 1185–1186, 1185*t*, 1186*f*
  - complications of, 1186–1187
  - management of, 1186–1187, 1187*t*
  - pathogenesis, 1185
- UTIs and, 1129, 1159

Bacteroides fragilis, infection after mid-urethral sling surgery, 2870–2871

Baden-Walker classification, of PFDs, 2529–2530

Baden-Walker Halfway Scoring System, 2588

Balanitis
- infection, 1288
- pseudoepitheliomatous, keratotic, and micaceous, 1299–1300, 1300*f*
- urethral reconstructive surgery for, 1811
- Zoon, 1302, 1303*f*

Balanitis xerotica obliterans (BXO), 875–876, 876*f*, 939, 940*f*

Balanoposthitis, 1288, 1289*f*

Ballistic lithotripsy, 2111–2112, 2112*f*

Balloon catheters, 173

Balloon dilation
    for achieving extraperitoneal access and developing extraperitoneal space, 209, 210*f*
    for ureteral stricture disease
        antegrade, 1967–1968
        results with, 1968
        retrograde, 1966–1967, 1967*f*–1968*f*
    for ureteroenteric strictures, 1977
Balloon dilators, 171–172, 171*f*–172*f*
Balloon incision, cautery wire, for ureteroenteric strictures, 1977
Barotrauma, during laparoscopic and robotic surgery, 225
Barrier function, of urothelium of bladder, 2467–2468, 2468*f*
Barrington nucleus, 2493
Bartter syndrome, 349, 2019
Basal cell carcinoma (BCC)
    as neoplastic condition, 1297–1298, 1300*f*
    of penis, 1772
Basal cells
    epididymis, 1374–1375, 1403–1404
    of prostate, 3278, 3278*f*
Base excision repair (BER), 1351.e1, 1351.e1*f*
Baseline urinary function, localized prostate cancer and, 3524
Bashful bladder
    detrusor underactivity and, 2659
    lower urinary tract dysfunction and, 2628–2629
Basic Laparoscopic Urologic Surgery (BLUS), 471
“Bayesian” problem, 3543
BBD, Bladder and bowel dysfunction
BCC, Basal cell carcinoma
BCG, Bacille Calmette-Guérin
BCI, Bladder contractility index

BCR, Bulbocavernosus reflex

BD, Behçet disease

BDL, Biomarker Development Laboratory

Beckwith-Wiedemann syndrome (BWS), genomic alterations in, 1098, 1354*t*

Behavior, norms of, masculinity and, 1416

Behavioral modification, for bowel-bladder dysfunction, 656

Behavioral therapy (BT)
- for enuresis, 663, 664*f*
- for OAB, 2647
- for urinary incontinence, in geriatric patient, 2920.e3

Behavioral training
- levels of evidence and recommendations for, 2722.e1*b*, 2722.e4*b*
- with urge suppression, 2727–2729, 2728*f*

Behavioral treatment programs, for urinary incontinence, 2722–2738, 2738*b*
- adherence to, 2734–2735
- assessment for, 2722–2723, 2723.e1*f*–2723.e2*f*, 2724*f*
- bladder training, 2728*f*, 2730–2732, 2730.e1*t*
- common, 2722, 2723*f*
- conditions benefitting from, 2722.e1*t*
- indications for, 2722
- levels of evidence and recommendations for, 2722.e1*b*, 2722.e4*b*
- lifestyle modifications as, 2722, 2722.e1*b*
- models of delivery, 2737–2738, 2737.e1*f*
- patient education for, 2723
- for pelvic floor dysfunction, 2732–2735
- pelvic floor muscle electrical stimulation, 2729–2730
- pelvic floor muscle training for, Pelvic floor muscle training
- for prevention, 2735–2736
- role of biofeedback in, 2727.e1*f*, 2729
- vaginal and urethral mechanical devices, 2736–2737

Behçet disease (BD), 1286–1287, 1287*f*

Bell-shaped curve, 480

Beneficence, definition of, 115

Benign bounce phenomenon, brachytherapy and, 3608

Benign cutaneous diseases, of external genitalia, of male genitalia

- angiokeratomas of Fordyce, 1302, 1303*f*
- ectopic sebaceous glands, 1303*f*, 1304
- median raphe cysts, 1304
- pearly penile papules, 1302, 1303*f*
- sclerosing lymphangitis, 1302–1304
- Zoon balanitis, 1302, 1303*f*

Benign disease, bladder surgery for, 3010–3047

- anatomy of, 3010
- bladder stones, 3043–3046
- diverticulectomy, 3010–3019, 3011*f*, 3011*b*, 3046*b*–3047*b*
- enterocystoplasty, 3034–3038
- foreign-body removal, 3043–3046
- partial cystectomy, 3038–3043
- psoas hitch and Boari flap, 3026–3034
- surgical considerations of, 3010
- urachal surgery, 3038–3043
- ureteral reimplantation, 3019–3026

Benign idiopathic urethrorrhagia, 401

Benign joint hypermobility syndrome, lower urinary tract dysfunction and, 2633

Benign lesions, adrenal, 2389–2394

- adenoma, 2362, 2389–2391, 2390*f*, 2391*b*
- adrenal cyst, 2393–2394, 2393*f*, 2394*b*
- ganglioneuromas, 2392–2393, 2393*b*
- myelolipoma, 2392, 2392*f*, 2392*b*
- oncocytoma, 2391, 2392*b*
- pheochromocytoma, Pheochromocytoma

Benign multilocular cyst, 765–766, 765*f*, 766*b*, 767*f*

Benign oncocytomas, 98

Benign prostatic hyperplasia (BPH), 3063, 3305–3342

acute urinary retention with, 3400–3401, 3400*t*
    as complication of, 3336–3339, 3337*f*–3339*f*, 3337*t*–3338*t*
α1-adrenergic blockers for, 3355–3356
    adverse events with, 3369
    alfuzosin, 3361–3363, 3362*t*
    anticholinergic receptor blockers with, 3389–3393, 3390*t*, 3392*f*
    cardiovascular diseases with, 3369–3370
    classification of, 3356–3357, 3356*t*
    comparison of, 3367–3369, 3368*t*
    complications associated with, 3370–3371
    doxazosin for, 3359–3361, 3360*t*–3361*t*
    in elderly, 3370
    hemodynamic side effects of, 3369, 3369*f*
    hypertension with, 3369–3370
    intraoperative floppy iris syndrome, 3370
    literature review for, 3357–3367
    naftopidil, 3365–3367, 3367*t*
    nonselective, 3356
    phosphodiesterase type 5 inhibitors with, 3393, 3394*t*
    rationale for, 3355–3356, 3355*f*
    safety profile of, 3369
    selective, 3356–3357
    sexual function and, 3370
    silodosin, 3365, 3365*f*, 3366*t*
    summary for, 3371
    tamsulosin, 3363–3365, 3363*f*, 3364*t*
    terazosin for, 3357–3359, 3357*t*–3358*t*, 3359*f*
α-adrenergic receptors in, 2500
β3-agonist (Mirabegron) for, 3381–3393
    indication, efficacy, and safety profile, 3381–3382
    phosphodiesterase type 5 inhibitors, 3382
alcohol use and, 3322
anatomic features of, 3313–3314, 3313*f*–3314*f*
androgen manipulation for, 3371–3379
    aromatase inhibitors for, 3377
    cetrorelix, 3377
    chlormadinone acetate, 3377
    dutasteride, 3374–3376, 3374*f*, 3375*t*, 3376*f*
    finasteride, 3371–3374, 3373*t*
    flutamide, 3376–3377
    literature interpretation for, 3371
    literature review for, 3371
    pharmacological classification for, 3371, 3372*t*

rationale for, 3371
5α-reductase inhibitors and sexual dysfunction, 3378
selective estrogen and androgen receptor modulators, 3377
summary for, 3379
tolerability and safety of, 3378
zanoterone, 3376
anticholinergic receptor blockers for
α-adrenergic blockers with, 3389–3393, 3390*t*, 3392*f*
β_3-agonists, 3393
autopsy prevalence of, 3317, 3317*f*
bladder obstruction in
measures of, 3320
response to, 3315–3316
body mass index and, 3324, 3325*t*
clinical prevalence of, 3317, 3318*f*
combination therapy for, 3385
α-adrenergic blockers and 5α-reductase inhibitors, 3385, 3386*f*
Combination of Avodart and Tamsulosin Study, 3386–3389, 3389*f*, 3389*t*
Medical Therapy of Prostatic Symptoms Trial, 3385–3386, 3387*f*–3388*f*, 3387*t*
complications of, 3335–3339
acute urinary retention with, as complication of, 3336–3339, 3337*f*–3339*f*, 3337*t*–3338*t*
bladder decompensation, 3335
bladder stones, 3335
hematuria, 3336
mortality, 3335
upper urinary tract deterioration and azotemia, 3336
urinary incontinence, 3335
urinary tract infections, 3336
cystourethrogram for, 3348
cystourethroscopy for, 3348
diagnostic evaluation of, 3343–3351, 3351*b*
diet and, 3324, 3325*t*
epidemiology of, 3316–3335, 3341*b*
analytical studies, 3320–3327
definitions for, 3316–3317
descriptive studies for, 3317–3320
parameter correlations, 3324–3327, 3326*f*–3327*f*, 3327*t*
etiology of, 3305–3313, 3316*b*
androgen receptors in, 3307
androgen role, 3306–3308, 3306*t*
cytokines, 3311, 3312*f*

  - dihydrotestosterone in, 3307–3308, 3308*f*
  - estrogen role in, 3308–3309, 3308*t*
  - familial factors in, 3311–3312, 3311*t*
  - genetic factors in, 3311–3312, 3311*t*
  - growth factors, 3309–3310, 3310*f*
  - hyperplasia, 3305–3306
  - inflammatory pathways in, 3311, 3312*f*
  - programmed cell death regulation, 3309
  - prolactin, 3313
  - signaling pathways in, 3310–3311
  - steroid 5α-reductase in, 3307–3308, 3308*f*
  - stromal-epithelial interaction, 3309

filling cystometry for, 3347

frequency-volume charts and bladder diaries of, 3344–3345

future directions for, 3401–3402, 3402*f*

health-related quality of life and, 3319

histologic features of, 3314–3315, 3314*f*

histologic prevalence of, 3317, 3317*f*

hypertension and, 3322

imaging for, 3347

instrumental investigations of, 3346–3351

laboratory tests of, 3345–3346

liver cirrhosis and, 3322

lower urinary tract function and, 2528

in lower urinary tract symptoms, 3305, 3306*f*

management of lower urinary tract symptoms caused by, 3351–3371
  - conservative, 3351, 3352*f*–3353*f*
  - lifestyle and dietary modifications, 3351–3353
  - watchful waiting, 3351

medical history for, 3343

medications and, 3324
  - effects of, 3404

metabolic syndrome and, 3324, 3325*t*

muscarinic receptor antagonists for, 3379–3381
  - efficacy of, 3379–3381, 3380*t*
  - rationale and indication for, 3379, 3379*t*
  - summary for, 3381
  - tolerability and safety profile of, 3381

natural history of, 3316–3335

obesity and, 3324, 3325*t*

pathology of, 3313–3315

pathophysiology of, 3313–3316, 3313*f*

phosphodiesterase type 5 inhibitors for, 3382, 3382*f*, 3383*t*–3384*t*, 3385*f*

- α1-adrenergic blockers with, 3393, 3394*t*

physical activity and, 3324, 3325*t*

physical examination for, 3344

phytotherapy for, 3393–3399

- current role of, 3395
- extract composition of, 3394, 3394*t*–3395*t*
- *Hypoxis rooperi* (South African star grass), 3398
- lycopene, 3398–3399
- mechanism of action, 3394–3395, 3395*t*
- origin of agents for, 3394, 3394*t*
- *Pygeum africanum* (African plum), 3398
- *Serenoa repens* (saw palmetto berry), 3395–3398, 3396*f*, 3397*t*
- summary for, 3399

postvoid residual volume for, 3346

pressure-flow study for, 3347

prostate and bladder imaging for, 3348

prostate size and, 3320, 3320*f*, 3404

prostate-specific antigen in, 3345

religion and, 3320–3321

serum creatinine measurement for, 3345–3346

sexual activity and, 3322, 3322*f*, 3323*t*

smoking and, 3324

smooth muscle in, 3315, 3315*f*

socioeconomic factors in, 3321, 3321*t*

surgery for, 3321, 3339–3340, 3340*f*

surgical treatment for, 3403–3404

symptom of

- assessment of, 3343–3344
- severity and frequency of, 3317–3319, 3319*f*

untreated, natural history of, 3327–3328

- baseline symptom severity in, 3331–3332
- clinical parameters of, 3328, 3328*t*
- disease progression in, 3332, 3332*f*–3333*f*, 3334*t*
- longitudinal population-based studies, 3333–3335, 3334*f*, 3334*t*–3335*t*
- outcomes of interest with, 3328, 3328*t*

        - perception of improvement, 3333
        - placebo control groups in, 3331, 3331*t*
        - placebo/sham effect in, 3331–3332
        - sham control groups in, 3331
        - study methods for, 3328–3335, 3329*t*
        - watchful waiting studies for, 3329–3330, 3330*f*, 3330*t*
    - upper-tract imaging for, 3347–3348
    - upper urinary tract in, deterioration of, 3336
    - urinalysis for, 3345
    - urodynamics for, 3347
    - uroflowmetry for, 3346–3347, 3346*f*
    - vasectomy and, 3322, 3322*f*, 3323*t*
- Benign prostatic obstruction (BPO), bladder outlet obstruction and, 2566
- Benign renal tumors, 2121–2132, Renal cysts
    - angiomyolipoma, 2125–2128, 2126*f*–2127*f*, 2128*b*
    - cystic nephroma, 2129–2130, 2129*f*
    - diagnosis of, 2121
    - leiomyoma, 2131, 2131*f*, 2131*b*
    - metanephric adenoma, 2128–2129, 2129*f*, 2129*b*
    - mixed epithelial and stromal, 2130, 2130*f*, 2130*b*
    - mixed mesenchymal and epithelial, 2129–2130, 2129*f*
    - oncocytoma, 2123–2125, 2124*f*, 2125*b*
    - other, 2131–2132, 2132*b*
    - papillary adenoma, of kidney, 2128, 2128*b*
- Benign urethral tumors, 1776
    - FEPs, 1776
    - hemangiomas, 1776
    - leiomyomas, 1776
- Benzodiazepines, to facilitate bladder emptying, 2720.e2
- BER, Base excision repair
- Berger disease, 17
- Beta-blockers, contrast media and, 32
- Bethanechol (Urecholine)
    - administration of, 2717

  for detrusor underactivity, 2660–2661
  efficacy of, 2718
  to facilitate bladder emptying, 2716–2717
  side effects of, 2718
  supersensitivity test, 2565
  ureteral response to, 1887

Bevacizumab, 1358, 3700
  for RCC, 2146, 2333–2334, 2333*t*

BEZ235, 3700

BF, Biofeedback

Bicalutamide, 3675

Bicarbonate reabsorption, in neonate, 342

Bicycle riding, long-distance, penile implants and, 1596, 1597*f*

Bifid pelvis, 737, 738*f*

Bifid scrotum, 886, 887*f*

Bifid ureters, 820–821

BII, BPH Impact Index

Bilateral anterior subcostal approach, for open kidney surgery, 2253

Bilateral renal agenesis (BRA), 714–717
  amniotic fluid production and, 716–717
  diagnosis of, 717
  gross pathologic description of, 715, 716*f*
  incidence of, 714
  mammalian kidney organogenesis in, 714–715
  phenotypic features associated with, 715–716, 717*f*
  postnatal radiographic evaluation of, 717
  prognosis of, 717
  renal embryology and possible etiology of, 714

Bilateral vanishing testes syndrome, 1005–1006

Bilirubin, in urine, 20

Binary survival outcomes, 104–105

Biochemical evaluation, of pheochromocytoma, 2376, 2377*f*, 2377*t*

Biochemical recurrence

- after radiation therapy, 3665–3670
    - androgen deprivation therapy after, 3668–3670
    - biopsy, 3666
    - imaging for, 3666–3667
    - natural history, 3666
    - prostate-specific antigen bounce, 3666
    - prostate-specific antigen recurrence, 3665–3666
    - salvage brachytherapy, 3668
    - salvage cryotherapy, 3667–3668, 3669*t*
    - salvage high-intensity focused ultrasound, 3668
    - salvage radical prostatectomy, 3667, 3667*t*
- after radical prostatectomy, 3659–3665
    - adjuvant radiation therapy, 3664–3665
    - androgen deprivation therapy, 3665
    - androgen deprivation therapy with salvage radiation therapy for, 3663–3664
    - definition of, 3659
    - imaging of, 3661–3662, 3662*f*
    - natural history of, 3660–3661
    - prediction of, 3659–3660, 3660*t*
    - salvage radiation therapy dose response, 3663
    - salvage radiation therapy for, 3662–3663
    - ultrasensitive prostate-specific antigen for, 3661
    - whole-pelvis *versus* prostatic bed radiation therapy, 3664, 3664*f*–3665*f*
- of prostate cancer, management strategies for, 3659–3670, 3670*b*

Bioethics, 115

Biofeedback (BF)

- for bowel-bladder dysfunction, 656–657
- for genito-pelvic pain-penetration disorder, 1653
- with PFMT, 2727.e1*f*, 2729, 2729*f*, 2729.e1*f*–2729.e2*f*

Biofilm, 434

- formation, 430, 434

BioGlue, 215.e2

Biologic grafts, for posterior compartment repair, 2829

Biologic therapies, for neuroblastoma, 1095–1096

Biologically active agents, 148

Biomarker Development Laboratory (BDL), 3478–3479

Biomarker Reference Laboratories (BRL), 3478–3479

Biomarkers
- for non-muscle-invasive bladder cancer, 3109, 3109*f*
- for penile cancer, 1759, 1759*t*
- telomerase activity as, 1364
- for testicular tumors, in pediatric patients, 1122, 1122*f*

Biopsy
- bladder, for RMS, 1113
- prostate, after radiotherapy for biochemical recurrence, 3666
- renal
  - laparoscopic, 2292, 2292*f*
  - ultrasound guidance of, 79–80
- for renal tumor ablation, 2314
- in retrograde ureteroscopic, 2212
- testis, 1454–1456
  - aspiration, percutaneous, 1455
  - complications of, 1456
  - indications of, 1454–1455
  - open testis biopsy: microsurgical technique for, 1455, 1456*f*
  - percutaneous, 1455
- in transurethral resection of bladder tumor, for non-muscle-invasive bladder cancer, 3096

Biopsy-based lesion identification, for focal therapy for prostate cancer, 3621

Biosyn suture, 149

Biothesiometry, 1527

Bipolar electrocautery, 466

Bipolar electrosurgical devices, 237
- for laparoscopic and robotic surgery, 214

Bipolar resectoscope, 172

Bipolar transurethral resection of the prostate (B-TURP), 3418–3420
- complications with, 3419
  - intraoperative, 3419

    - perioperative, 3419
    - postoperative, 3419
  - concept for, 3418–3419
  - conclusion for, 3419–3420
  - outcomes with, 3419
    - comparative studies, 3419
    - single-cohort studies, 3419
  - technique for, 3419
- Birmingham Reflux Study (Birmingham Reflux Study Group 1987), 515
- Birt-Hogg-Dubé (BHD) syndrome, genomic alterations in, 1354*t*, 1358, 2142*t*, 2144–2145
- BISF-W, Brief Index of Sexual Function for Women
- Bisphosphonates, for castration-resistant prostate cancer, 3703–3704
- Bites, animal and human, penile, 3050
- Bladder, 315*f*, 324*f*
  - afferent pathways in, 2481–2486, 2487*b*
    - cannabinoids, 2486
    - in detrusor underactivity, 2653–2655, 2655*f*
    - functional properties of, 2482–2483, 2483*f*
    - modulators of, 2483–2484
    - nitric oxide in, 2484, 2484*f*
    - pelvic organ interactions with, 2486, 2486*f*
    - properties of, 2481
    - purinergic signaling, 2484–2485, 2485*f*
    - spinal cord pathways of, 2481–2482, 2481*t*, 2482*f*
    - transient receptor potential cation channels, 2485
  - aging and, 2509–2510
  - anatomy of, 2461–2513, 2462*f*, 3010
    - lamina propria of, 2462–2463
    - smooth muscle of, 2465, 2465*f*
    - stroma of, 2463
    - urothelium of, 2461–2462, 2462*f*–2463*f*, Urothelium, of bladder
    - vasculature of, 2462–2463, 2464*f*
  - capacity of
    - nocturnal, 661–662
    - pharmacologic therapy to increase, 2679–2700
    - reconstruction and, 681–682
  - cells, receptivity in UTIs, 1136–1137, 1137*f*

changes, during pregnancy, 1185
closure of, for classic bladder exstrophy, 545–548, 546*f*–548*f*
contractility of
  bladder emptying and, 2716–2718
  pharmacologic therapy to inhibit, 2679–2700
contraction of
  muscarinic receptors and, 2679–2681
  normal, in voiding, 2515–2516
decompensation, in benign prostatic hyperplasia, 3335
defects in, in bladder exstrophy, 535–537, 536*f*–537*f*
defunctionalized, lower urinary tract dysfunction and, 2632–2633
development of, 329–333, 333*b*
dynamics of, 681–682
dysfunction of, 680–681
  with posterior urethral valves, 616–619
efferent pathways to, 2487–2493, 2487*f*
  adrenergic, 2488
  in detrusor underactivity, 2653, 2655*f*
  glutamate in, 2488, 2489*f*
  glycine and γ-aminobutyric acid in, 2488
  purinergic, 2488–2489
  reflex circuitry, 2489–2493, 2490*f*
  serotonin in, 2488–2489
  terminal nerve fibers, 2487–2488
  transmitters in, 2488, 2490*b*, 2491*f*–2492*f*, 2491*t*
emptying failure of, 2903–2904, 2903*b*–2904*b*
  absorbent products for, 2904
  catheterization for, 2900–2902, 2900*f*
  external collecting devices for, 2903–2904
  intravesical pressure increases for, 2902–2903
emptying of
  benign prostatic hyperplasia and, 3354–3355
  failure of, 2518–2519
  reconstruction and, 682
  therapy to facilitate, 2520*b*
  urodynamic studies of, 2564–2566
estrogens and, 2503
filling of, Continence
  abnormalities of, 2516–2519, 2516*b*–2517*b*, 2518*t*
  bladder response during, 2514–2515
  mechanics of, 2478–2479

    - outlet response to, 2515
    - smooth muscles in, 2478
    - urodynamic studies of, 2552*t*–2553*t*, 2559
- in genitourinary tuberculosis, 1309
- glycosaminoglycan layer, 1232.e5–1232.e7, 1232.e7*b*
- high-pressure, spinal cord injury with, host defense mechanisms in UTIs and, 1140
- injuries of, 3054–3057, 3055*b*–3056*b*
    - clinical signs and symptoms of, 3056
    - complications with, 3057
    - diagnosis of, 3055–3056
    - etiology of, 3054–3055
    - with holmium laser enucleation of prostate, 3438
    - management of, 3056–3057, 3056.e1*f*
    - outcomes with, 3057
    - radiographic imaging of, 3055–3056, 3055*f*
- male
    - circulation of, 2456
    - innervation of, 2456
    - relationship with, 2448*f*
    - trigone, 2455–2456, 2456*f*
    - ureterovesical junction of, 2455–2456, 2456*f*
- mesh perforation of, in midurethral sling, 2868–2870, 2868*f*, 2869*t*, 2870*b*
- natural defenses of, 1138–1139
- necrosis of, with transurethral vaporization of prostate, 3426
- neoplasia in, 1360–1361
- neural tube defects and, early intervention for, 628, 628*f*
- obstruction of
    - response to, 3315–3316
    - RMS causing, 1113
- overactive, Overactive bladder
- paralytic, 2522
- perforation of
    - after augmentation cystoplasty, 700–701, 700*f*
    - in transurethral resection of bladder tumor, 3135, 3135*f*
- pharmacology of, 2497–2503
    - adrenergic mechanisms, 2500–2501, 2501*f*, 2501*b*
    - muscarinic mechanisms, 2497–2500, 2499*t*, 2500*b*
    - sex steroids, 2502–2503
- physical examination for, 10, 10*f*–11*f*
- in prune-belly syndrome, 582–583, 584*f*

- pudendal nerve stimulation and, 2511
  - inhibitory and excitatory frequencies for, 2511
- reconstruction of, 690–691
  - after RMS treatment, 1116
- regeneration of, for augmentation cystoplasty, 706
- sensation of
  - altered, filling/storage failure due to, 2517–2518
  - detrusor underactivity and, 2659
  - terminology for, 2581
- sensory input of, pharmacologic therapy to decrease, 2679–2700
- smooth muscle of, 1185, 2465, 2465*f*
- storage failure of, 2517–2518, 2903–2904, 2904*b*
  - absorbent products for, 2904
  - augmentation cystoplasty for, 2889–2890
  - external collecting devices for, 2903–2904
- storage function of
  - after retropubic suspension surgery, 2770
  - pharmacologic therapy to facilitate, 2679–2716
  - urinary incontinence and, 2581
  - urodynamic studies of, 2552*t*–2553*t*, 2559
- suburothelial interstitial cells of, 2470, 2470*f*
- surgical considerations of, 3010
- transabdominal pelvic ultrasonography, 80–81, 80*f*–81*f*
- transurethral resection of, 1198–1199
- trigone of, 2455–2456, 2456*f*
- tumors of, Bladder tumors
- underactive, 2506–2507, 2650
  - parasympathomimetics for, 2660–2661
  - pediatric, 660
- unstable, 2637
- UPEC persistence in, 1136–1137, 1138*f*
- urothelium of, genetic alterations in, 1360–1361
- voiding of, Micturition
  - bashful bladder, 2628–2629
  - mechanics of, 2479

Bladder advancement flap, laparoscopic or robotic, 3031, 3033*f*

Bladder and bowel dysfunction (BBD), 397–399, 495
- conservative management of, 656

  - neuromodulation for, 658, 659*t*
  - in pediatric patients, 654
  - pharmacotherapy for, 657–658
  - treatment for, 655–656
  - urotherapy for, 655–656

Bladder anomalies, in children, 518–527
  - acquired, 525–526, 527*b*
    - inflammatory, 526
    - noninflammatory, 525–526
  - congenital, 518–525, 523*b*
    - embryology of urinary bladder, 518
    - normal and abnormal antenatal sonographic findings of bladder, 518–525

Bladder augmentation, pharmacologic therapy in, to facilitate bladder filling and urine storage, 2718

Bladder calculi
  - after renal transplantation, 2117
  - bladder outlet obstruction with bladder lithiasis, 2115–2116
  - etiopathogenesis of, 2114–2115
  - lithotripsy
    - for EHL, 241
    - pneumatic, 244.e4
  - medical management of, 2066–2067
  - in patients with spinal cord injury, 2116–2117
  - in urinary diversions and augmented bladder, 2116

Bladder cancer
  - BCG in, 1333, 1334*f*, 1338–1339, 1339*f*
  - bladder diverticula with, 2969–2971, 3011
  - chronic inflammation role in, 1336–1338, 1337*f*–1338*f*
  - diminished bladder capacity and, 2671
  - DNA methylation in, 1349
    - *CDH1* and *RASSF1A* genes, 1350
    - hypermethylation, 1350
    - hypomethylation, 1350
    - *INK4A* gene, 1350
  - genomic alterations in, 1358–1360
    - alterations in normal and benign urothelium, 1360–1361

    - detection and surveillance using, 1361
    - before neoplasia, 1360–1361
  - in geriatric patients, 2920.e12–2920.e13
  - hereditary, 3076
  - immune checkpoint blockade in, 1342
  - immunotherapy for, 1333
  - long-term indwelling catheterization and, 2616
  - metastatic
    - chemotherapy for, 3127*t*
    - FDA-approved agents and future directions for, 3130
    - first-line, immune checkpoint inhibitor therapy, 3130
    - immune checkpoint inhibitor therapy, 3129–3130
    - management of, 3112–3132, 3131*b*
    - multiagent, second-line chemotherapy for, 3129
    - randomized trials in, 3127–3128, 3127*t*
    - second-line, immune checkpoint inhibitor therapy, 3130
    - second-line chemotherapy for, 3128, 3128*t*
    - single agent, second-line chemotherapy for, 3128–3129, 3129*t*
    - targeted therapy for, 3130–3131
  - minimally invasive, 3144
  - as non-AIDS-defining urologic malignancy, 1268
  - in nuclear medicine, 43
  - screening for, molecular genetics-based assays for, 1361
  - UTUC after, 2192–2193
- Bladder cancer, pediatric
  - in augmented bladders, 1118
  - carcinoma, 1118
  - TCC, 1117–1118
  - urachal carcinoma, 1118
- Bladder coil, 174*f*
- Bladder compliance (C), 2478
  - after augmentation cystoplasty, 697–698, 697*f*
  - impaired, urodynamic studies of, 2560–2561, 2560*f*–2561*f*
- Bladder contractility index (BCI), 2567, 2567*f*, 2659
- Bladder cooling reflex, 2485
- Bladder cuff

  - management, 2200
  - open distal ureterectomy with excision of, 2204

Bladder diary, 3
  - for behavioral treatment programs, 2723, 2724*f*
  - for benign prostatic hyperplasia (BPH), 3344–3345
  - Questionnaire-Based Voiding Diary, 2723, 2723.e1*f*–2723.e2*f*
  - for urinary incontinence, male, 2541, 2541*f*

Bladder diverticula, 509–510, 509.e1*f*, 2964–2972, 2965*f*–2966*f*
  - associated conditions, 2969–2971
    - bladder outlet obstruction, 2969
    - endoscopic examination, 2969, 2970*f*
    - ipsilateral vesicoureteral reflux, 2971
    - malignancy, 2969–2971
  - classification of, 2964–2965
  - diagnosis of, 2965–2969, 2971*b*
    - evaluation of, 2965–2967, 2966*f*
    - imaging of, 2965*f*, 2967, 2968*f*–2969*f*
    - presentation of, 2965–2967, 2966*f*
    - urodynamics of, 2967–2969
  - etiology of, 2964–2965
  - malignancy, 3011
  - management of, 2971–2972, 2972*b*, 2973*f*
    - endoscopic, 2972
    - indications for intervention, 2972
    - observation and nonsurgical, 2972
  - nonsurgical management of, 2972
  - pathophysiology of, 2964–2965
  - surgical management of, laparoscopic and robotic diverticulectomy, 2972
  - techniques for repair, complication with, 2991, 2991*f*

Bladder diverticulectomy, 3010–3019, 3011*f*, 3011*b*, 3046*b*–3047*b*
  - complications of, 3018–3019
  - evaluation of, 3011–3012, 3012*f*
  - laparoscopic and robotic techniques, 3015–3018, 3016*f*–3017*f*
  - outcomes of, 3018–3019
  - postoperative care of, 3018–3019
  - surgical indications, 3011–3012, 3012*f*
  - surgical technique of, 3012–3018, 3012*f*

Bladder duplication, 521–522, 521*f*

Bladder dysfunction, after pediatric renal transplantation, 1063

Bladder epithelial grafts, 1806

Bladder exstrophy, 330, 379–380, 381*f*

- recommendations for, 379–380

Bladder filling, ureteral function effects of, 1893

Bladder function

- localized prostate cancer and, 3524
- in prune-belly syndrome, 596–600

Bladder functional assessment, for ureteral anomalies, 806

Bladder health promotion research, for LUTS prevention, 2735–2736

Bladder hemangiomas, 525

Bladder imaging, for benign prostatic hyperplasia, 3348

Bladder infections, 1166*b*

- complicated, 1158–1159, 1158*f*, 1158*t*
- emphysematous cystitis, 1158–1159
- recurrent UTIs, 1159–1166, 1160*t*, 1160*b*
    - bacterial persistence, 1160–1161
    - cranberry, 1163–1164, 1164*f*
    - D-mannose, 1166
    - estrogen, 1164–1165, 1164*f*
    - immunoactive prophylaxis, 1166
    - low-dose continuous prophylaxis for, 1162–1163
    - management, 1161–1166, 1161*f*
    - methenamine, 1165–1166, 1165*t*
    - non-antibiotic management, 1163
    - probiotics, 1165
- uncomplicated cystitis, 1155–1158
    - antimicrobial selection for, 1156–1157
    - clinical presentation, 1156
    - follow-up, 1157–1158
    - laboratory diagnosis, 1156
    - management, 1156–1157, 1157*f*
    - risk factors, 1156*b*
- unresolved UTIs, 1159, 1159*b*

Bladder injury
  complications of seminal vesicle surgery, 1863
  and intraoperative consultation, 299–300, 303*b*
    diagnosis/recognition, 300
    incidence, 299, 299*t*
    management, 300
    mechanisms, 299–300, 300*t*
  during laparoscopic and robotic surgery, 230.e1
  perforation/extrusion and, 2882–2883, 2882*f*
Bladder mobilization, for ureteral reimplantation, 3021, 3021*f*
Bladder mucosa, in vesicovaginal fistula repair, 2940, 2941*f*
Bladder neck, 1807.e4*f*, 1807.e8
  division of, 690
  in laparoscopic radical prostatectomy
    identification and transection of, 3573, 3573*f*
    reconstruction of, 3577
  mesh perforation/extrusion at, 2883, 2883*b*, 2884*f*–2885*f*
  in neuromuscular dysfunction of lower urinary tract, 637
  in retropubic radical prostatectomy
    division of, 3559–3560, 3560*f*–3561*f*
    reconstruction and anastomosis of, 3560–3562, 3561*f*–3562*f*
Bladder neck closure
  in classic bladder exstrophy
    failure of, 563–564, 564*b*
    outcomes and results of, 558–559, 559*t*, 559*b*, 560*f*
  for vesicoureteral reflux, 2615
Bladder neck contracture
  after photoselective vaporization of prostate, 3441
  after retropubic radical prostatectomy, 3564
  with bipolar transurethral resection of prostate, 3419
  with holmium laser enucleation of prostate, 3438
  with monopolar transurethral resection of prostate, 3417
Bladder neck dysfunction, 2519
  lower urinary tract dysfunction and, 2627–2628
  videourodynamics for, 2570, 2570*f*

Bladder neck reconstruction

- artificial urinary sphincter for, 687–688
- bladder neck division for, 690
- bulking agents for, 687
- fascial sling for, 686–687
- Pippi Salle procedure for, 690, 691*f*
- urethral lengthening for, 688–690, 689*f*
- in urinary tract reconstruction, 685–690, 690*b*
- Young-Dees-Leadbetter repair for, 685–686

Bladder neck slings, for neuromuscular dysfunction of lower urinary tract, 637

Bladder neck stenosis, after transurethral microwave therapy, 3430

Bladder neck stricture, in robotic prostatectomy, 3580

Bladder outlet

- closure of, 2898, 2899*f*
- overactivity of, emptying/voiding failure from, 2519
- response of, to filling, 2515
- storage failure at, 2890–2898, 2898*b*
  - adjustable continence therapy, 2895, 2895*f*
  - adverse events of, 2893
  - bladder outlet closure, 2898, 2898*b*, 2899*f*
  - cell-based therapy, 2895–2898
  - complications of, 2895
  - human studies, 2896
  - injectable agents for male stress urinary incontinence, 2896–2897
  - injection techniques of, 2891–2893, 2892*f*
  - outcomes of, 2895
  - patient selection, indications, and contraindications, 2891
  - periprocedure care of, 2893
  - urethral bulking agents, 2890–2895
- surgery of, for detrusor underactivity, 2662–2663
- underactivity of
  - emptying/voiding failure from, 2518–2519
  - filling/storage failure from, 2518
- ureteroceles and, 806–807, 807*f*–808*f*

Bladder outlet obstruction (BOO)

- after pubovaginal sling procedure, 2845–2848, 2848*b*
  - surgical management of, 2846–2848, 2847*t*

- in benign prostatic hyperplasia, medical treatment and, 3354
- with bladder diverticula, 2964–2965
- detrusor underactivity and, 2655–2656, 2657*b*
- emptying/voiding failure from, 2519
- in geriatric patients, 2920.e7
- mechanisms of, 2505–2506, 2506*b*
- in mesh complication, 2880
- nocturia and, 2671–2673
- urodynamic studies of
  - in men, 2566–2567, 2567*f*
  - in women, 2567–2568
- videourodynamic studies of
  - in women, 2570, 2570*f*
- in women, lower urinary tract dysfunction and, 2628

Bladder output relation (BOR), 2566, 2566*f*

Bladder pain syndrome (BPS), 2517–2518
- female sexual dysfunction and, 1657
- overactive bladder distinguished from, 2637, 2638*f*
- terminology for, 2637

Bladder pain syndrome and interstitial cystitis (BPS/IC), 1224–1250
- definition of, 1224, 1225*f*–1226*f*, 1226*b*
- diagnosis of, 1225*b*, 1233, 1234*t*, 1235*f*, 1236*b*, 1239*b*
  - markers in, 1238
  - potassium chloride test, 1238–1239
- epidemiology of
  - associated disorders, 1230–1231, 1230*t*, 1231*f*, 1231*b*
  - natural history, 1228–1229, 1230*b*
  - prevalence, 1226, 1227*t*–1228*t*, 1229*b*
- etiology of, 1231–1232, 1232*f*, 1232.e11*b*
  - animal models, 1232.e1
  - antiproliferative factor, 1232.e7, 1232.e8*b*
  - autoimmunity and inflammation, 1232.e2–1232.e3, 1232.e3*b*
  - bladder glycosaminoglycan layer and epithelial permeability, 1232.e5–1232.e7, 1232.e7*b*
  - genetics, 1232.e10
  - infection, 1232.e1–1232.e2
  - mast cells and histamine, 1232.e4–1232.e5, 1232.e5*b*
  - neurobiology, 1232.e7–1232.e9, 1232.e9*b*
  - nitric oxide metabolism, 1232.e9

    - other potential causes, 1232.e10–1232.e11
    - pelvic organ cross-sensitization, 1232.e9, 1232.e9*b*
    - urine abnormalities, 1232.e9–1232.e10
  - historical perspective of, 1224–1225, 1225*b*
  - mechanisms of, 2507–2509, 2509*b*
  - nomenclature, 1224
  - pathology, 1232–1235, 1233*b*
  - surgical therapy for, 1247–1248, 1249*b*
    - historical procedures, 1247–1248
    - for Hunner lesion, 1248
    - hydrodistention, 1247
    - major procedures, 1248
    - surgical considerations, 1247
  - taxonomy, 1224, 1225*f*
  - treatment of, 1239*b*
    - conservative therapies, 1239–1240
    - diet, 1240–1241, 1240*b*
    - intravesical therapies, 1241*t*, 1244–1247, 1245*b*
    - neuromodulation, 1246–1247, 1247*b*
    - oral therapies, 1241–1244, 1241*t*, 1244*b*
    - surgical therapy, 1247–1248, 1249*b*
  - urgency, 1225–1226, 1226*f*, 1226*b*
  - urine studies
    - biopsy, 1236–1238, 1237*f*
    - clinical assessment and research, 1235.e1, 1235.e1*b*
    - office cystoscopy, 1236, 1237*f*
    - urodynamic evaluation, 1235–1236
    - voiding diary, 1235
- Bladder recurrence, UTUC after, 2193
- Bladder retraining, types of, 3352
- Bladder RMS, 1111
  - biopsy of, 1113
  - epidemiology and syndromic associations of, 1111
  - imaging evaluation of, 1113–1114
  - pathology and molecular biology of, 1111–1113, 1112*f*, 1113*b*
  - presenting symptoms and examination of, 1113–1117, 1113*t*, 1113*b*
  - staging and COG risk group assignment of, 1113–1114, 1114*t*
  - treatment of, 1115*b*

        - COG multimodal approaches to, 1114–1115
        - European Cooperative Group approaches to, 1115
        - evolution of multimodal, 1114
        - late effects of, 1116–1117
        - outcomes of, 1116
        - surgical reconstruction, 1116
        - for very young children, 1116

Bladder spasm, 932

Bladder sphincter function, effects of sex reassignment surgery on, 3062–3063

Bladder stones, 243.e1, 244.e3–244.e4, 3043–3046

    - with benign prostatic hyperplasia, 3335
    - complications of, 3046
    - endourologic approach to, 2115, 2116*f*
    - evaluation of, 3043–3044
    - laparoscopic and robotic technique, 3044–3045, 3045*f*–3046*f*
    - management of, 2115
        - medical, 2115
    - open surgery for, 2115
    - open technique of, 3044, 3045*f*
    - percutaneous, 3045–3046
    - postoperative care of, 3046
    - presentation of, 2115
    - surgical indication of, 3043–3044
    - surgical technique of, 3044–3046

Bladder surgery, for genitourinary tuberculosis treatment, 1317–1318

Bladder training

    - evidence for, 2730
    - for urinary incontinence, 2722.e2*b*–2722.e4*b*, 2728*f*, 2730, 2730.e1*t*

Bladder tumor antigen (BTA) assay, of bladder tumor, 3079–3081

Bladder tumors, 3073–3090, 3078*b*

    - benign, 3010–3047
        - anatomy of, 3010
        - bladder stones, 3043–3046
        - diverticulectomy, 3010–3019, 3011*f*, 3011*b*, 3046*b*–3047*b*
        - enterocystoplasty, 3034–3038
        - foreign-body removal, 3043–3046

      - partial cystectomy, 3038–3043
      - psoas hitch and Boari flap, 3026–3034
      - surgical considerations of, 3010
      - urachal surgery, 3038–3043
      - ureteral reimplantation, 3019–3026
  - benign, pediatric, 1119
  - nonurothelial malignancy, 3089–3090, 3089*f*
      - prostatic urethral cancer, 3084
      - sarcomas, Sarcomas, of bladder
  - during pregnancy, and urologic malignancy, 293

Bladder urinary diversion, rectal, 3209–3211
  - augmented valved rectum, 3209
  - folded rectosigmoid bladder, 3209
  - hemi-Kock pouch procedures with valved rectum, 3209–3210
  - Mainz II pouch, 3210–3211
  - sigma-rectum pouch, 3210–3211
  - T pouch procedures with valved rectum, 3209–3210, 3210*f*

Bladder wall
  - collagen of, 2463–2464
  - elastin of, 2464
  - matrix of, 2464
  - stroma of, 2463

Bladder wall thickness (BWT), 3348

Blake drains, 148

Bland thrombus, IVC filtration and permanent interruption for, 2277

Bleeding
  - after midurethral sling, 2874
  - during anterior colporrhaphy, 2782
  - complication of scrotal surgery, 1855
  - in monopolar transurethral resection of prostate, 3415
  - with prostate biopsy, 3499
  - at the sheath site, 226–227, 227*f*

Bleomycin, for penile cancer, 1771

Bleomycin-etoposide-cisplatin (BEP), for seminomas, 1705

Blind access, 169

Blind trocar placement, complications related to, 225–226

α-Blockade, for pheochromocytoma, 2378, 2379*f*

β-Blockade, for pheochromocytoma, 2378, 2379*f*

α-Blockers

- for nocturia, 2674
- transurethral microwave therapy *versus*, 3429

Blockers of inhibition, to facilitate bladder emptying, 2719

Blood-based biomarkers, for prostate cancer, 3480–3485

Blood-epididymis barrier, 1404

Blood/hematuria, 16

- differential diagnosis and evaluation of, 16

Blood loss/transfusion, in robotic prostatectomy, 3580

Blood pressure, anesthesia-related changes in, during laparoscopic and robotic surgery, 228.e1

Blood products

- transfusions, preoperative considerations for, for laparoscopic and robotic surgery, 204
- for urologic surgery, 147–148

Blood-testis barrier, 1373, 1398–1399, 1399*f*

Blood tests, for male urinary incontinence, 2543

“BLUE stent,”, 834–835, 834*f*

Blunt dissection instrumentation, for laparoscopic and robotic surgery, 218

Blunt trauma

- renal, 1982
  - imaging of, 1984
  - nonoperative management of, 1986–1987
  - renal artery thrombosis with, 1990
- ureteral, 1992, 1992*t*
  - diagnosis of, 1992–1993

BLUS, Basic Laparoscopic Urologic Surgery

BMI, Body mass index

Boari flap, 3026–3034

- with bladder advancement flap, 3031
- complications with, 3032
- evaluation for, 3026
- laparoendoscopic single-site, 3031
- laparoscopic or robotic, 3030–3031, 3030*f*–3031*f*
- for lower ureteral injuries, 1999, 2000*f*
- with mega-Boari flap, 3033*f*
- outcomes with, 3033–3034
- postoperative care of, 3032
- surgical indication for, 3026
- surgical technique for, 3027–3028, 3028*f*
- with ureteroneocystostomy, 1973

Body habitus, hormonal therapy and, 3681

Body mass index (BMI)

- benign prostatic hyperplasia and, 3324, 3325*t*
- in bladder tumor, 3076
- male SUI and, 2540–2541
- prostate cancer and, 3465, 3465*f*
- urinary incontinence and, 2582

Body weight, renal calculi and, 2027–2028

Bone mineralization, renal regulation of, 1914, 1914*f*

Bone morphogenic protein-7 (BMP-7), in tubulointerstitial fibrosis, 787

Bone scan, for localized prostate cancer, 3527

Bone scan index, 3679

Bone-anchored porcine single-incision sling, 2843

Bone-anchored sling, history and development of, 2994

Bony pelvis

- female, 2427, 2428*f*
- male, 2444

BOO, Bladder outlet obstruction

BOR, Bladder output relation

Bors-Comarr classification, of voiding dysfunction, 2522–2523, 2523*b*

Bosniak category IV lesions, 770

Bosniak classification, for renal cystic lesions, 2122, 2122*f*, 2122*t*, 2137, 2137*t*

Botox, for chronic scrotal pain syndrome, 1221

Bottleneck technique, 1845, 1847*f*

Botulinum toxin (BoNT), OnabotulinumtoxinA

- adverse effects of, 2709
- for bowel-bladder dysfunction, 658
- clinical use of, 2708
- for detrusor underactivity, 2662
- efficacy of, 2709
- to facilitate bladder emptying, 2720.e3
- to facilitate bladder filling and urine storage, 2682*t*, 2707–2709
- mechanism of action of, 2707–2709
- for neuromuscular dysfunction of lower urinary tract, 634–635
- for OAB, 2647
- for Parkinson disease, 2606
- for prostatic injections, 3447

Botulinum-A toxin, for PE, 1572.e3

Bowel cleansing, before inguinal node dissection, 1801

Bowel disorders, normal *versus* abnormal, 667, 668*t*

Bowel dysfunction, in geriatric patients, 2920.e9

Bowel entrapment, during laparoscopic and robotic surgery, 230

Bowel function

- localized prostate cancer and, 3525
- urinary incontinence and, 2734

Bowel injury, 275–281, 276*f*

- duodenal and pancreatic injuries, during nephrectomy, 277, 277*f*

- during laparoscopic and robotic surgery, 228*f*, 229
- laparoscopic kidney surgery causing, 2307, 2307*f*
- lymphoceles, 280–281, 281*f*
- management, 278
- mechanism of, 276–277
- port site hernia, 278, 278*f*–279*f*
- rectal injury, 277–278
- in robotic prostatectomy, 3580
- venous thromboembolism, 278–280, 279*t*–280*t*

Bowel insufflation, during laparoscopic and robotic surgery, 224

Bowel interposition, for ureteral injuries, upper, 1998, 1998*f*

Bowel mobilization, in transurethral resection of bladder tumor, 3137, 3137*f*

Bowel obstruction, 3272
- with intestinal anastomoses, 3180–3181, 3180*t*, 3181*f*

Bowel preparation
- preoperative, for laparoscopic and robotic surgery, 204
- for urinary tract reconstruction, 682
- in urologic surgery, 124–125

Bowel resection, orthoptic urinary diversion and, 3238–3239

Bowen disease, of penis, 1742, 1742.e1*f*

Bowenoid papulosis
- as neoplastic condition, 1296, 1298*f*
- of penis, 1742

BP, Bullous pemphigoid

BPH, Benign prostatic hyperplasia

BPH Impact Index (BII), 110*t*
- for benign prostatic hyperplasia, 3344

BPO, Benign prostatic obstruction

BPS, Bladder pain syndrome

BPS/IC, Bladder pain syndrome and interstitial cystitis

BRA, Bilateral renal agenesis

Brachytherapy, 3632–3638

- benign bounce phenomenon and, 3608
- combined with external irradiation, 3613–3615
- external beam radiation therapy *versus*, 3612–3613, 3614*t*
- outcomes for, 3612
- for penile cancer, 1765–1767, 1767*f*–1768*f*
- for prostate cancer, 3591, 3596–3600, 3600*b*
  - combined with external irradiation, 3599–3600
  - high-dose-rate, 3598–3599
  - low-dose-rate, technique and trends of, 3596, 3597*f*
  - patient selection for, 3599
  - permanent implant quality assessment, 3597–3598, 3597*f*, 3598*t*
  - transrectal ultrasound-guided, 3591–3592, 3592*f*

Bradley classification, of voiding dysfunction, 2524

Brain circuits, in detrusor underactivity, 2653, 2655*f*

Brain metastases, of TGCTs, 1706–1707, 1707*b*

Brain tumor

- lower urinary tract dysfunction with, 2604
- neurogenic bladder with, 648

Brainstem

- bladder modulatory mechanisms of, 2493–2494, 2495*f*
  - neurotransmitters and modulators within, 2495–2496
- neuromuscular lower urinary tract dysfunction at and above, 2602–2607

Brainstem stroke, lower urinary tract dysfunction with, 2603

Branchio-oto-renal syndrome, 336–337

Bricker anastomosis, 3187, 3187*f*

Brief Index of Sexual Function for Women (BISF-W), 112, 112*t*

Brindley system, 2741–2742

Bristol Female Lower Urinary Tract Symptoms (BFLUTS) Questionnaire, 110

Bristol Stool Scale, 473–474, 474*f*, 667–668, 668*f*

BRL, Biomarker Reference Laboratories

Broad ligament, 2430, 2431*f*

Brödel-type orientation, 162, 163*f*

Brushite calculi, surgical management of, 2076

- stone fragility and, 2077.e1

Brushite stone formers, 2011–2012, 2013*f*

Brushite stones, surgical management of, method selection for, 2077.e2

BT, Behavioral therapy

B-TURP, Bipolar transurethral resection of the prostate

Buccal mucosa, in complex penile reconstruction, 946

Bulbar urethra, 1807.e8

Bulbocavernosus reflex (BCR), in pelvic floor disorders, 2530

Bulbospongiosus, 2435

Bulbourethral artery, 1383

Bulbourethral glands, 1383

Bulbous urethra, 1383, 1383*f*, 1807.e2*f*, 1807.e4*f*

Bullous pemphigoid (BP), 1284–1285, 1285*f*

Bumetanide, in stone formation, 2033

Bupropion

- for female sexual arousal disorders, 1650
- for female sexual interest disorder, 1645

Burch colposuspension, 2763–2766, 2766*b*

- Marshall-Marchetti-Krantz procedure *versus*, 2773
- paravaginal repair *versus*, 2766
- prophylactic colposuspension, 2765
- pubovaginal sling *versus*, 2771, 2772*f*
- reoperative surgery, 2765–2766
- results with, 2763–2765
- suspensions in, configuration of, 2758
- technique for, 2763, 2764*f*

    urethral elevation in, 2758

Buried penis, 394, 877–878, 878*f*–879*f*

Burns, of penis, 3053

Buschke-Löwenstein tumor, 1742.e1*f*, 1742.e3

Buspirone, for female sexual interest disorder, 1645

BWS, Beckwith-Wiedemann syndrome

BWT, Bladder wall thickness

BXO, Balanitis xerotica obliterans

Byars flap procedure, 927, 931*f*

Bypass techniques, for vena caval thrombectomy, 2275–2276, 2275*f*–2276*f*, 2275.e1*f*, 2276.e1*f*

C

C3 complement, in prostatic secretions, 3298*t*, 3302

CA, Cryoablation

Cabazitaxel, 3692–3693, 3693*f*

Cabozantinib, 3701
  for RCC, 2337, 2338*f*
C-acetate PET/CT, 43
Cadaveric fascia lata
  allograft slings and, 2834–2835
  for pelvic organ prolapse reconstructive surgery, 2781*t*–2782*t*, 2786, 2786*f*
Cadaveric models, laparoscopic training with, 232
Cadherins, in prostate growth regulation, 3288
Caffeine reduction
  for OAB, 2647
  for urinary incontinence, 2733
CAH, Congenital adrenal hyperplasia
Caiman 5 vessel-sealing system, 214.e1*f*
Cake or lump kidney, 728*f*–729*f*, 729
Calcifying nanoparticles (CNPs), 2011
Calcitonin gene-related peptide (CGRP)
  and ED, 1499
  in ureteral function, 1887
Calcium
  filtrate transport, 1911, 1912*f*
  metabolism of, 2015–2016
  in pediatric kidney stone disease, 869
  in prostate cancer, 3463–3465
  PTH and, 1914, 1914*f*, 2016
  sensitization to, 2472–2473
  in smooth muscle contraction, 2472–2473, 2472*b*, 2473*f*, 2475–2476, 2476*f*
  in ureter physiology
    excitation-contraction coupling and, 1884–1885
    as second messengers, 1885–1887, 1885*f*–1886*f*
  vitamin D and, 1914, 2015
Calcium antagonists

    - to facilitate bladder filling and urine storage, 2682*t*, 2696–2697
    - urethral function effects of, 1903
- Calcium apatite, 2011
- Calcium-based calculi in, 2048–2049, 2049*b*
    - dietary, 2049
- Calcium channel blockers (CCBs)
    - and ED, 1507
    - for pheochromocytoma, 2379–2380, 2379*f*
    - ureteral function effects of, 1900
- Calcium channels, in detrusor muscle, 2474–2475, 2475*f*
- Calcium hydroxylapatite (Coaptite), for female urinary incontinence, 2894–2895
- Calcium-induced calcium release (CICR), 2476
- Calcium oxalate stones
    - of crystal formation, 2010
    - formation of, 2008
    - formers of, 2011–2012
    - homogeneous nucleation, 2011
    - Randall plaques and, 2011, 2012*f*–2013*f*, 2018
    - surgical management of, 2076
        - stone fragility and, 2077.e2
- Calcium stones, in renal calculi, 2018–2026
    - hypercalciuria, 2018–2020
    - hyperoxaluria, 2020–2023, 2021*f*–2022*f*
    - hyperuricosuria, 2023–2024, 2024*f*
    - hypocitraturia, 2024
    - hypomagnesiuria, 2026
- Calculi
    - after augmentation cystoplasty, 699

  - anesthesia-related, during laparoscopic and robotic surgery, 228.e1
  - pneumoperitoneum causing, 221
- Cardiac glycosides, urethral function effects of, 1903–1904
- Cardiac ischemia, during vena caval thrombectomy, 2278
- Cardinal ligament, 2429–2430, 2431*f*

Cardinal veins, retrocaval ureter and, 1963, 1966*b*

Cardiopulmonary bypass (CPB), for vena caval thrombectomy, 2275–2276, 2275*f*–2276*f*, 2276.e1*f*

Cardiovascular disease (CVD)

- α-blocker therapy in patients with, 3369–3370
- and ED, 1504
- erectile dysfunction and, 1425–1426, 1426*b*
- prostatitis and, 1210
- renal calculi and, 2008–2009

Cardiovascular morbidity/mortality, hormonal therapy and, 3681

Cardiovascular system

- abnormalities of, with cloacal exstrophy, 575
- pneumoperitoneum effects on, 220–221
- Wilms tumor treatment effects on, 1108

Carnitine, for PD, 1611, 1616*t*

Carter-Thomason needle-point suture passer, 219, 219*f*

Caruncle, urethral, urethral diverticula differentiated from, 2987, 2987*f*

Casale continent catheterizable stoma, 711, 712*f*

Caspases, in GU cancers, 1365–1366

Castration-resistant prostate cancer

- anaplastic phenotype, 3705
- assessment of, 3687–3689
- bisphosphonates for, 3703–3704
- clinical considerations for, 3687–3690, 3690*b*
- cytotoxic chemotherapy for, 3690–3693, 3694*b*
  - chemotherapeutic agents as, 3690–3693
  - evaluation of treatment efficacy, 3690
  - platinum agents as, 3693
- epidural cord compression in, 3702
- immunotherapy for, 3697–3699, 3699*b*
  - immune checkpoint blockade as, 3698
  - pembrolizumab, 3698–3699
  - ProstVac-VF, 3698

    - sipuleucel-T, 3697–3698, 3697*f*
  - metastatic, 3689–3690
  - neuroendocrine subtype, 3704–3705
  - nonmetastatic, 3689
  - novel hormonal therapies for, 3693–3696, 3696*b*
    - androgen receptor modulation as, 3695–3696, 3695*f*
    - AR-V7 as, 3696
    - CYP17 inhibition as, 3693–3695, 3694*f*
  - palliative management of, 3702–3704, 3705*b*
    - bone-targeted approaches as, 3703–3704
    - pain and spinal cord compression as, 3702, 3703*t*
  - prognostic considerations for, 3687–3689, 3688*f*
  - radiopharmaceuticals for, 3704
  - RANK ligand inhibitors for, 3704
  - targeted treatments for, 3699–3702, 3702*b*
    - angiogenesis, 3700–3701
    - apoptosis pathway in, 3701–3702
    - DNA repair, 3702
    - MET signaling, 3701
    - PI3K/Akt/mTOR pathway in, 3699–3700
  - treatment for, 3687–3706

Casts, in urine, 23, 23*f*–24*f*

Catch bonds, 1135

Catecholamine hypersecretion, in evaluation of adrenal masses, 2402–2403, 2402*t*

Catecholamine synthesis blockade, for pheochromocytoma, 2378–2379, 2379*f*

Catecholamine testing, for pheochromocytoma, 2377

Catecholamines, adrenal medulla physiology and, 2358–2360, 2359*t*–2360*t*

Category I cysts, 769

Category II cysts, 769

Category III cysts, 769–770

Catheter-associated bacteriuria, UTIs and, 1190, 1191*b*

Catheter-associated UTI (CAUTI), 433

Catheter placement, for urodynamics, 2535

Catheterization
- anatomic considerations in, 152
- for bladder emptying failure, 2900–2902, 2900*f*
  - continuous, 2901–2902
- of children, urethral, 153
- difficult, 156–158
- history of, 152
- lower urinary tract, 152–159
  - technique of, 152–155
- in men, urethral, 153
- preparation for, 152–153
- suprapubic, 155–156
- ureteral, 1197
- urethral, antimicrobial prophylaxis for urologic procedures and, 1197
- in women, urethral, 153

Catheterized urine specimens, in urine collection, 1141

Catheters
- air-charged, for urodynamic studies, 2558
- condom, 155
- diagnostic, 154–155, 155*f*
- double-lumen, 154
- drain, 155
- hematuria, 154, 154*f*
- indwelling, in geriatric patients, 2919
- knotting and balloon malfunction, 159
- long-term, bladder cancer and, 2616
- single-lumen, 154
- sizing, 153–154, 154*t*
- types of, 153–155
- water-filled, for urodynamic studies, 2558

Cation transport, urinary tract obstruction and, 794

Cauda equina, 2619

Cauda equina syndrome, 2620

Cauterization, energy modalities for, 235–241
  electrosurgery, 235–241, 236*f*
  ultrasound instrumentation, 237–238
Cautery wire balloon incision, for ureteroenteric strictures, 1977
CAUTI, Catheter-associated UTI
CAVD, Congenital absence of vas deferens
Caveolae, in ED, 1499
Cavernosal nerves, 1378
Cavernosal veins, 1807.e5*f*
Cavernosogram, of penis, 1386, 1387*f*
Cavernous smooth muscle content test, 1525
Cavitation mechanism, in ultrasonography, 77
Cavoplasty, for IVC, 2276, 2277*f*
CBCL, Child Behavior Checklist
CBE, Classic bladder exstrophy
CCBs, Calcium channel blockers
C-choline and F-fluorocholine, 43
CCI, Charlson Comorbidity Index
CCSK, Clear cell sarcoma of kidney
CDC, Centers for Disease Control and Prevention
CDH1 gene, in bladder cancer, 1350
CDKIs, Cyclin-dependent kinase inhibitors
CDKN1B, in UTUC, 2197
Cecil-Culp repair, for hypospadias fistula, 947*f*
Cecocystoplasty, 694
Cecum, proximal, 3211
Celecoxib, urethral function effects of, 1903

Cell adhesion molecules, in prostate growth regulation, 3287–3288, 3288*b*

Cell-based therapy, of male stress urinary incontinence, 2897

Cell cycle deregulation, in GU cancers, 1347–1348, 1349*b*

- CDKIs, 1347.e1, 1347.e1*f*
- cell cycle entry, 1347.e1
- cell cycle progression through S phase, 1347.e2
- cyclin-dependent kinases and cyclins, 1347.e1, 1347.e1*f*
- G_1/S checkpoint, 1347.e2
- G2M checkpoint, 1347.e2–1347.e3
- mitosis, 1347.e2
- mitotic arrest and spindle assembly checkpoint, 1347.e3
- RB1, 1347.e1, 1347.e1*f*
- S phase arrest, 1347.e2
- TP53, 1347.e2, 1347.e2*f*, 1348

Cell cycle markers, in UTUC, 2197

Cell cycle progression, in prostate cancer, 3543

Cell differentiation, in UTUC, 2197

Cell migration and invasion, in UTUC, 2197

Cell proliferation, in UTUC, 2197

Cells, in urine, 21–23, 21*f*–23*f*

CellSearch system, 3484–3485, 3485*f*

Cellular proliferation, 305

Cellules, 2967

Cellulitis, 1288–1289, 1290*f*

- genital skin loss and, 3053

Centers for Disease Control and Prevention (CDC), 1251

Central defect, in pelvic floor support mechanism, 2597–2598

Central perineal tendon, 1807.e10

Central venous pressure, pneumoperitoneum effects on, 221

Cephalad renal ectopia, 724–725, 726*f*

Cephalexin, for UTIs, 1170*t*

Cephalosporins

- prophylaxis with, for uncomplicated urologic procedures, 1194*t*–1196*t*
- for UTIs, 1151*t*–1153*t*, 1154, 1187*t*

Cerebellar ataxia, lower urinary tract dysfunction with, 2604

Cerebral palsy (CP)

- lower urinary tract dysfunction with, 2604–2605
- pathogenesis of, 647–648
- presentation of, 647, 650*b*
- specific recommendations of, 648

Cerebrovascular accident (CVA), lower urinary tract dysfunction and, 2602–2603

Cerebrovascular disease, lower urinary tract dysfunction and, 2602–2603

Cernilton, 3399

- for diminished bladder, 2674

Cervical atresia, 984–985, 985*f*

Cervical myelopathy, lower urinary tract dysfunction with, 2617

Cervical RMS, in pediatric patients, 1120

Cervix, 325, 325*f*

- anatomy of, 2436

Cesarean delivery, urinary incontinence and, 2583

Cetrorelix, for benign prostatic hyperplasia, 3377

CEVC, Clinical Epidemiological Validation Center

CGA, Comprehensive geriatric assessment

cGMP, Cyclic guanosine monophosphate

CGRP, Calcitonin gene-related peptide

Chancroid, 1255*t*, 1259–1260, 1259*f*

Chaperone-usher pathway (CUP), 428–429

Chaperonin, androgen receptor binding of, 3289

Charlson Combined Comorbidity Index, 107–108

Charlson Comorbidity Index (CCI), 2909, 3522

Checkpoint inhibition, in GU cancers, 1367–1368, 1368*b*

Chemical exposure, in workplace, 1416

Chemodenervation, for urinary incontinence, in geriatric patients, 2920.e5

Chemokines, 1333–1334, 1335*f*, 1335*t*

Chemotherapy
- for bladder tumor, 3077
- for castration-resistant prostate cancer, 3690–3693
  - cabazitaxel, 3692–3693, 3693*f*
  - docetaxel, 3690–3692, 3691*f*–3692*f*
  - mitoxantrone, 3690, 3693*f*
- for metastatic bladder cancer, 3125
  - second-line, 3128, 3128*t*
- for metastatic RCC, 2341–2342
- for muscle-invasive bladder cancer, 3121–3123, 3121*t*
  - randomized trials in, 3127–3128, 3127*t*
- for neuroblastoma, 1093*f*, 1095
- at PC-RPLND, 1727
- for penile cancer, 1769–1771, 1772*b*
  - adjuvant, 1771
  - combination, 1770–1771
  - single-agent, 1769–1770
  - surgical consolidation after, 1771
- with radiation therapy, for locally advanced prostate cancer, 3654–3655
- for RCC, resistance to, 2145
- for retroperitoneal tumors, 2245–2247, 2246*t*
- for TGCTs
  - with brain metastases, 1706–1707, 1707*b*
  - NSGCTs, 1695
  - post-salvage, 1701
  - relapsed tumors, 1700
  - residual mass management after, 1698–1700, 1698*t*–1699*t*
  - seminomas, 1704, 1704*t*
  - toxicity of, 1707

- for UTUC, 2222–2223, 2223*f*
- for Wilms tumor, 1100, 1102*f*

Chest, imaging of, for TGCTs, 1690

Chest X-ray, 450

Chevron and subcostal incision, kidney and retroperitoneum approaches, 137–138, 139*f*

Chevron incision, for open kidney surgery, 2253

Chief complaint, in patient history, 1

Child Behavior Checklist (CBCL), 477, 654

Childbearing women, prevention of urinary incontinence and, 2735

Childhood diseases, and male infertility, 1432–1434

Children

- fundamentals of
  - MRI in, 412–413
  - sonography in, 404
- ionizing radiation in, 403
- megaureter in, 849–852, 852*b*
  - cutaneous ureterostomy for, 850–851, 850*f*
  - definition of, 849
  - definitive reconstruction for, 850–851, 850*f*
  - dilatation and stenting for, 852
  - etiology, occurrence, and presentation of, 849
  - excisional tapering for, 851–852, 851*f*
  - Kalicinski plication technique for, 851, 851*f*
  - outcomes with, 852
  - remodeling for, 837*f*–839*f*, 851
  - Starr plication technique for, 851, 851*f*
  - surgical indications for, 849–850
  - surgical management of, 850–852, 850*f*–851*f*
  - ureteral polyps with, 835–836
  - ureteral strictures with, 835
- surgery of ureter in, 826–852
- ureteropelvic junction obstruction in, 826–836
  - associated anomalies, 826
  - clinical presentation of, 826, 827*f*
  - complications with, 832*f*, 835, 835*f*
  - definition of, 826

    - dismembered pyeloplasty, 828, 828*f*–830*f*
    - endoscopic approach to, 830
    - flank approach to, 829
    - laparoscopic pyeloplasty for, 830–834, 833*f*–834*f*
    - lower pole, 826, 827*f*
    - minimally invasive techniques for, 830–835
    - nondismembered pyeloplasty for, 828–829, 829*f*–831*f*
    - outcomes with, 835
    - posterior lumbotomy for, 829, 832*f*
    - secondary, 826
    - surgical approach to, 829
    - surgical indications for, 826–827
    - surgical repair of, 827–828
  - urethral catheterization of, 153
  - UTI in, 426
    - diagnosis of, 426*b*
  - vesicoureteral reflux in, 836–846, 836*b*
    - clinical presentation of, 836
    - Cohen Cross-Trigonal technique for, 840, 841*f*
    - complications of ureteral reimplantation for, 844–846
    - definition of, 836
    - early complications of, 844–846
    - endoscopic treatment of, 846–849
    - extravesical procedures for, 840–842, 842*f*–843*f*
    - Glenn-Anderson technique for, 840, 840*f*
    - incision for, 836, 837*f*–839*f*
    - intravesical procedures for, 836–840
    - long-term complications of, 846
    - minimally invasive procedures for, 842–844
    - Politano-Leadbetter technique for, 837*f*–839*f*, 840
    - postoperative evaluation of, 844
    - reoperative reimplantation for, 846
    - robotic-assisted laparoscopic ureteral reimplantation- extravesical for, 844, 845*f*
    - surgical management of, 836

- Children's Oncology Group (COG)
  - staging systems and risk group assignments of
    - for bladder RMS, 1113–1114, 1114*t*
    - for testicular tumors, 1122, 1122*t*
  - treatment recommendations of, bladder RMS approaches, 1114–1115

- Chills, patient history of, 7

- *Chlamydia*

  - as fastidious organism in UTIs, 1133
  - as nongonococcal urethritis, 1253

Chronic pyelonephritis, 1176–1177, 1177*f*

Chronic renal failure, and ED, 1511

Chronic scrotal pain
  - complication of scrotal surgery, 1855
  - surgical management of, 1853–1855, 1854*f*

Chronic scrotal pain syndrome, 1219–1220, 1222*b*
  - nonmedical therapy for, 1221
  - nonradical surgical treatments, 1221
  - surgical therapy, 1221–1222, 1223*f*

Chylous ascites
  - after RPLND, 1731, 2244
  - laparoscopic and robotic surgery causing, 231.e1

Chyluria
  - as filariasis clinical manifestation, 1330
  - nephrolysis for, 2294, 2294*f*

CIC, Clean intermittent catheterization

CICR, Calcium-induced calcium release

Cidofovir, for condylomata acuminata, 1742.e3

CIQ-FLUTS, International Consultation on Incontinence Questionnaire Female Lower Urinary Symptoms

Circle nephrostomy tube, 174*f*

Circulating tumor cells (CTCs), as prostate cancer biomarkers, 3484–3485, 3485*f*

Circulating tumor DNA, as prostate cancer biomarkers, 3484–3485, 3485*f*

Circumcision, 393, 872–876, 873*b*
  complications of, 873–874, 874*f*, 876*b*
    urethral reconstructive surgery and, 1811–1812
  female, 987–988, 988*f*
  penile cancer management with, 1752–1753
  for penile carcinoma, prevention of, 1743
  for posterior urethral valves, 615
  for prune-belly syndrome, 593
Circumferential compression mechanism, of stone fragmentation, 2096–2097
CIS, Carcinoma in situ
Cisapride, to facilitate bladder emptying, 2718
Cisplatin
  for penile cancer, 1770
  for TGCTs, toxicity of, 1707
Citrate
  in crystal formation, 2014, 2024
  in pediatric kidney stone disease, 869
Citric acid, in prostatic secretions, 3295
Citrus juices, for hypocitraturia, 2053–2054
CJD, Creutzfeldt-Jakob prion disease
CKD, Chronic kidney disease
Classic bladder exstrophy (CBE), 290–291
  abdominal wall defects in, 533
  anatomic considerations in, 531–537
  anorectal defects in, 533
  antireflux procedure for, 554–556, 555*f*–556*f*
  chordee in, 551
  complete repair for, 544, 544*f*
    continence outcomes with, 560
    technical aspects of, 550, 550*f*
  continence procedure for, 554–556, 555*f*–556*f*
  continence with, 565

continent urinary diversion for, 564–565, 565*b*
epispadias repair for, 550–551
  failure of, 564
evaluation of, at birth, 539–542, 539*f*, 539*b*
female genital defect in, 534–535, 535*f*
fertility, 290–291
genital anatomy, 290
immobilization techniques for, complications of, 542–543, 543*t*, 543*b*
Kelly repair for, 544
  continence outcomes with, 561
  technical aspects of, 549–550, 549*f*
long-term adjustment issues with, 567–568, 568*b*
male genital defect in, 533–534, 533*f*–534*f*
management of, at birth, 539–542, 539*f*
Mitchell repair for, 544, 544*f*
  continence outcomes with, 560
  technical aspects of, 550, 550*f*
mode of delivery, 291
modern staged repair of exstrophy, 545
  bladder, posterior urethral, and abdominal wall closure for, 545–548, 546*f*–548*f*
  combined bladder closure and epispadias repair, 548
  management after, 548–549
osteotomy for, 540–542, 541*f*–542*f*
  complications of, 542–543
outcomes and results of modern initial repair, 556–559
  bladder neck repair, 558–559, 559*t*, 559*b*, 560*f*
  epispadias repair, 557–558
  initial closure, 557
pelvic bone defects in, 531–532, 531*f*
pelvic floor defects in, 532, 532*f*
penile reconstruction for, 551–552, 552*f*–553*f*
penile skin closure for, 552–554
pregnancy, 291
reconstruction failures and complications, 561–565
  epispadias repair, 564
  failed bladder neck repair, 563–564, 564*b*
  failed closure, 561–563, 561*f*–562*f*, 561*t*, 563*b*
Schrott-Erlangen approach to, 545
  continence outcomes with, 560

  - spinal defects in, 531–532
  - surgical options in newborn with, 543–545
    - Mainz repair, 545
  - surgical reconstruction of, 538–556
    - alternative, 564–565
    - female exstrophy, 554
    - patient selection for, 540
    - postoperative care, 556
    - postoperative problems, 554
    - small exstrophy bladder unsuitable for newborn closure, 540
  - ureterosigmoidostomy for, 564
  - urethral reconstruction for, 564
  - urinary defects in, 535–537, 536*f*–537*f*
- Classic Wilms tumor, 1100, 1100*f*
- Classical Cushing syndrome, 2363, 2363*f*, 2364*t*
- Clavien-Dindo scale, 260–261, 261*t*
- Clavien-Dindo System of Classifying Complications, 105–106, 106*t*
- Clean intermittent catheterization (CIC)
  - for bladder emptying failure, 2901
  - for bowel-bladder dysfunction, 657
  - for renal transplantation, 1057
  - for urinary tract infections, 625
- Cleansing enema, for prostate biopsy, 3496
- Clear cell RCC
  - chemotherapy, 2341–2342
  - familial form of, 1354*t*, 1358, 2141–2143, 2143*t*, 2144*f*
  - hormonal therapy, 2342–2343
  - immunologic approaches to, 2329–2332
    - allogeneic hematopoietic stem cell transplantation, 2331, 2331*t*
    - IL-2, 2329–2331, 2330*t*
    - immune checkpoint inhibitors, 2331–2332, 2332*f*
    - interferons, 2329, 2329*t*
  - pathology of, 2149*t*–2151*t*, 2151–2152, 2152*f*
  - targeted molecular therapies for
    - basis of, 2332–2333, 2333*f*
    - combination and sequential therapy with, 2339–2341

        - immune “checkpoint” inhibitor-based combination strategies, 2341, 2342*f*
        - mTOR pathway inhibitors, 2326–2327, 2338–2339, 2340*f*, 2340*t*
        - other, 2341–2343
        - VEGFR-based, 2326–2327, 2333–2337, 2333*t*–2335*t*, 2336*f*, 2337*t*
- Clear cell sarcoma of kidney (CCSK), in pediatric patients, 1108–1109
- Clenbuterol, for stress urinary incontinence in women, 2714

Congenital curvature of penis, 1836–1837

Congenital defects *versus* acquired scar, 498–499

Congenital disorders, and delayed ejaculation, 1575

Congenital diverticula, 522

  urethral, reconstructive surgery for, 1810

Congenital megacystis, 376–377, 519–521, 519*f*, 520*t*

Congenital mesoblastic nephroma (CMN), in pediatric patients, 1109

Congenital nephrosis, 756

Congenital nephrotic syndrome (CNS), 345

Congenital nephrotic syndrome of Finnish type (CNF), 756

Congenital neurogenic bladder, diagnostic evaluation and follow-up of, 631, 631*f*, 632*t*

Congenital penile curvature, 914, 917*f*

Congenital penile nevi, 883, 883*f*

Congenital strictures, 1815

Congenital unilateral absence of the vas deferens, 1449–1450

Congenital urethral fistula, 883, 883*f*

Conn syndrome, adrenal surgery for, 2409–2410, 2409*b*

Connexin 43, 2476–2477, 2477*f*

Conservative therapies, for BPS/IC treatment, 1239–1240

Constipation, Defecation disorders

Constitutional symptoms, patient history of, 7

Consultation, intraoperative, 296–304, 298*b*

Contact dermatitis, 1276–1277, 1277*f*

Content validity, 109

Contextual features, definition of, 116

CONTILIFE, 111*t*

Continence

  during abdominal pressure increases, 2516

- after creation of neobladder, 3272–3273, 3272*t*
- after orthoptic urinary diversion, 3251–3254, 3252*t*–3253*t*, 3254*b*
- bladder expansion in, 2593, 2593*b*
- bladder outlet in, 2593–2595
- in cloacal exstrophy, 579–580
- estrogens and, 2713
- lower urinary tract neural control in, 2593
- in male epispadias, 569–570, 570*t*
- mechanisms of, 2593–2595
  - development of, 329–333
- medical diagnoses and, 2527
- physiotherapy, role of, in laparoscopic radical prostatectomy, 3579
- procedure, for classic bladder exstrophy, 554–556, 555*f*–556*f*
- promotion and advocacy for, 2920.e9
- reflex circuitry controlling, 2489–2493, 2490*f*
  - somatic to visceral reflexes, 2492
  - sphincter to bladder reflexes, 2490*f*, 2491–2492, 2492*f*
  - storage phase, 2490–2491, 2490*f*–2491*f*, 2491*t*
- sphincteric mechanisms in, 2593–2595
  - female, 2594–2595, 2595*b*
  - male, 2594, 2594*f*, 2595*b*

Continent catheterizable channels, for bladder emptying failure, 2898–2900, 2899*f*

Continent catheterizable stoma, 292

Continent catheterizing pouches, 3211–3226, 3212*f*

- continent ileal reservoir, 3213–3215, 3214*f*
- double T pouch, 3215, 3216*f*–3217*f*
- gastric pouch, 3225–3226, 3225*f*–3226*f*
- general care, 3213
- general procedural methodology, 3212–3213
- Indiana pouch, 3220–3224, 3222*f*–3223*f*
- Mainz pouch I, 3215–3219, 3218*f*–3221*f*
- Penn pouch, 3224–3225, 3224*f*
- right colon pouches with intussuscepted terminal ileum, 3219–3220

Continent ileal reservoir, 3213–3215, 3214*f*

Continent urinary diversions, 191, 3208–3226
  catheterizable stoma for, 706–711
  for classic bladder exstrophy, 564–565, 565*b*
  considerations for, 706
  continent vesicostomy, 710–711
  cutaneous, 3206–3232, 3231*b*
    absorbable stapling techniques in, 3227–3228
    comments on, 3208
    continent catheterizing pouches, 3211–3226, 3212*f*
    cystectomy for, 3206–3208, 3207*f*
    general considerations of, 3206
    operative technique variations for, 3227–3229
    patient preparation of, 3206
    patient selection of, 3206
    postoperative care of, 3208
    quality-of-life assessments, 3226–3227
    rectal bladder urinary diversion, 3209–3211
  flap valves for, 707–709
  hydraulic valves for, 710
  ileocecal valve for, 709–710
  mechanisms for, 706–711, 707*f*
  Mitrofanoff principle for, 707–709
  nipple valves for, 707
  for pediatric patients, 706–713, 711*b*
    considerations to, 706
    results with, 709
    technique for, 708–709, 708*f*
  ureterosigmoidostomy for, 706–707
Continent vesicostomy, 710–711
Continuous incontinence, patient history of, 5
Continuous occlusion test, 2659
Continuous positive airway pressure (CPAP)
  for nocturnal polyuria, 2669
  for obstructive sleep apnea, 2920.e8
Continuous urinary incontinence, 2540, 2581
Continuous wave lasers, 238

Contractile activity, of ureters, 1883–1887, 1883*f*
    calcium and excitation-contraction coupling, 1884–1885
    proteins, 1883–1884, 1883*f*–1884*f*
    second messengers in, 1885–1887, 1885*f*–1886*f*
    urothelial effects on, 1885
Contractile (motor) function, in overactive bladder, 2640
Contractile proteins
    of smooth muscles, 2470–2472, 2471*f*–2473*f*
    of ureters, 1883–1884, 1883*f*–1884*f*
Contractile tissue, epididymal, 1403*f*, 1404
Contralateral internal ring, 892, 892*f*
Contrast agents, in ultrasonography, 76–77
Contrast media, 29–35, 35*b*
    adverse reactions, 29–34, 30*t*
    allergic-like reactions, 30
    considerations, 32–34
    contrast reactions, treatment of, 30–31
    delayed contrast reactions, 32
    magnetic resonance imaging contrast agents, 34–35
    premedication, 31–32, 31*b*
Contrast nephropathy, 1923–1924
Contusion, ureteral, 1996
Convective radiofrequency water vapor thermal therapy, 3421–3422
    complications of, 3422
    conclusion for, 3422
    outcomes with, 3422
        comparative studies, 3422
        single-cohort studies, 3422
    technique for, 3421–3422, 3421*f*–3422*f*
Conventional radiation, 3587
Conventional radiography, 28, 29*f*, 29*b*, 415
    intravenous pyelography, 415

    plain abdominal radiography, 415
    retrograde pyelography, 415
Convergent validity, 109
Cooper ligament, 2444, 2447*f*–2448*f*
Cope catheter, 173, 173*f*
Cope retention mechanism, 173
Copy number alterations (CNAs), in GU cancers, 1354, 1354*t*–1355*t*
Cordonnier and Nesbit techniques, in urinary diversion, 3187
Corpora amylacea, 1203
Corpora cavernosa, 1383–1384
    anatomy of, 1807.e1*f*–1807.e2*f*
Corporal perforation, 1589–1591, 1590*f*
Corpus cavernosum electromyography, and single potential analysis of cavernous electrical activity, 1527
Corpus spongiosum, 1383–1384
    anatomy of, 1807.e1*f*–1807.e3*f*, 1807.e6*f*–1807.e7*f*
Cortical defects, vesicoureteral reflux, 498–501, 500*b*
    acquired renal scars, 499–500
    congenital defects *versus* acquired scar, 498–499
    pathophysiology of acquired scarring, 500–501, 500*f*–501*f*
    reflux-associated renal dysplasia, 499, 499*f*, 499*t*, 499.e1*f*
Cortical microcystic disease, 756–757
Cortical renal scan with DMSA, 440
Cortical sex cords, 319*f*
Corticobasal degeneration, lower urinary tract dysfunction and, 2631
Corticosteroids
    in genitourinary tuberculosis medical therapy, 1316–1317
    and nephrotic syndrome, 345, 348*b*
Corticotropin-releasing factor (CRF), 2495–2496

Cortisol hypersecretion, testing for, 2399–2401

Corynebacterial infection, as cutaneous disease of external genitalia, 1292–1293, 1293*f*

CoSeal, 215.e2

COU-AA-301 study, 3694, 3694*f*

Cough leak point pressure (CLPP), 2562

Council catheters, 153, 173*f*

Cowden syndrome, 2142*t*, 2145

COX-2 inhibitors
  - to facilitate bladder filling and urine storage, 2703
  - urethral function effects of, 1903
  - for urinary tract obstruction, 795

CP, Cerebral palsy

CPAP, Continuous positive airway pressure

CPB, Cardiopulmonary bypass

CPDN, Cystic partially differentiated nephroblastoma

CPPS, Chronic pelvic pain syndrome

CPR, Concentration product ratio

Cranial suspensory ligament (CSL), 318–320

Creatinine
  - GFR and, 777, 1905, 1906*f*
  - serum
    - for benign prostatic hyperplasia, 3345–3346
    - measurement, in AKI, 1921, 1922*t*

Creatinine clearance (CrCl), GFR estimation with, 1905

Credé maneuver, 2902

Creep, ureteral, 1891

Cremasteric artery, 1370–1371, 1372*f*, 1375, 1393

Cremasteric muscle, 1394*f*

Creutzfeldt-Jakob prion disease (CJD), allografts and, 2835

CRF, Corticotropin-releasing factor

Criterion validity, 109

Crossed renal ectopia, 727–728, 727*f*–728*f*, 731*b*

Cross-organ sensitization, 2486, 2508

Cross-sectional imaging, of pheochromocytoma, 2375

Cryoablation (CA)

- for locally advanced prostate cancer, 3655
- for renal tumors, 2309–2310, 2310*b*
    - background and mode of action, 2309–2310
    - complications of, 2318–2319, 2320*f*–2321*f*, 2320*b*
    - duration, 2310
    - follow-up for, 2312–2314, 2314*b*
    - freeze-thaw cycles, 2310
    - laparoscopic, 2304
    - oncologic outcomes of, 2314–2318, 2315*t*–2316*t*, 2318*b*
    - percutaneous, 2312, 2313*f*, 2318
    - RFA *versus*, 2317–2318
    - success of, 2313–2314, 2314*f*
    - treatment temperature, 2310

Cryotherapy, 3624–3628, 3625*f*, 3627*t*

Cryptorchidism, 321, 322*f*–323*f*, 413*f*, 949, 972*b*, 1432–1433, 1440, 1449
- acquired, 949, 954
- adjuvant hormonal therapy for, 965
- associated pathology of, 961–964
  - epididymis anomalies with, 962–963, 962*f*
  - gubernacular anomalies with, 962–963
  - processus vaginalis anomalies with, 962–963
  - testicular anomalies with, 963–964
  - testicular maldevelopment, 961–964
- cancer risk and, 1680
- congenital, 949, 953–954
- definitions for, 949
- diagnosis of, 958–964
  - nonpalpable testes, 959–961, 960*f*
  - palpable testes, 958–959, 959*f*
- diagnostic laparoscopy for, 960–961
- epidemiology of, 953–954
- etiology, diagnosis and management of, 949–958
- examination in, 958, 958*f*
- genetic susceptibility to, 954–955
- hormonal defects of, 950*f*, 956–957
- hormonal evaluation of, 960
- human chorionic gonadotropin for, 964–965
- imaging of, 960
- luteinizing hormone-releasing hormone for, 964–965
- management of, 959*f*, 964
- medical management of, 964–965
- MRI of, 415
- pathogenesis of, 954–958
- prognosis for, 968–972
- surgical management of, 965–968
  - abdominal testis, 967–968
  - palpable testis, 966–967
- syndromic, 957–958
- testicular cancer and, 970–972
- testicular embryology and, 949–953

  - testicular hormone production for, 950–951, 950*f*
  - ultrasonography of, 412, 412*b*

Crystallization
  - inhibitors and promoters of, 2014–2015
  - in urine, 2009

Crystals
  - aggregation of, 2011
  - homogeneous nucleation of, 2011
  - oxidative stress and, 2013–2014
  - retention of, 2011
  - scanning electron micrographs of, 2041, 2042*f*
  - in urine, 23, 24*f*

CSL, Cranial suspensory ligament

CT, Computed tomography

CT urogram (CTU), for genitourinary tuberculosis diagnosis, 1312, 1313*f*

CTA, Computed tomography angiography

CTCAE, Common Terminology Criteria for Adverse Events

“CTC-Chip,”, 3485

CTCL, Cutaneous T-cell lymphoma

CTCs, Circulating tumor cells

CTLA-4, Cytotoxic T-lymphocyte antigen-4

CTV, Clinical target volume

Culp-DeWeerd spiral flap, for ureteropelvic junction obstruction, 1960–1961, 1961*f*

CUP, Chaperone-usher pathway

Curriculum, for men's health center, 1427

Curvatures of penis, 394, 880–881, 881*f*
  - correction of, 306–310, 311*f*
  - reconstructive surgery for, 1836–1838, 1838*b*
    - acquired, 1837–1838

        - congenital, 1836–1837

- Cushing disease, 2361
- Cushing syndrome, 2360–2367, 2367*b*
    - ACTH-dependent, 2361, 2361*f*
        - Cushing disease, 2361
        - ectopic ACTH syndrome, 2361, 2362*f*, 2362*t*, 2366
        - treatment of, 2365–2366, 2366*f*
    - ACTH-independent, 2362, 2366–2367
        - bilateral macronodular adrenal hyperplasia, 2362

- virus-related, 1742.e2–1742.e3, 1743*b*

Cutaneous T-cell lymphoma (CTCL), as neoplastic condition, 1302, 1302*f*

“Cut-to-the-light” procedure, 3059

CVA, Cerebrovascular accident

CVD, Cardiovascular disease

CxBladder, of bladder tumor, 3081

CyberWand, 245

Cyclic adenosine monophosphate (cAMP), in ureteral contractions, 1885

Cyclic guanosine monophosphate (cGMP), in ureteral contractions, 1885

Cyclic guanosine monophosphate-signaling pathway, 1497–1499

Cyclin D2, 3616

Cyclin-dependent kinase inhibitors (CDKIs), in GU cancers, 1347.e1, 1347.e1*f*

Cyclin-dependent kinases, in GU cancers, 1347.e1, 1347.e1*f*

Cyclins, in GU cancers, 1347.e1, 1347.e1*f*

Cyclooxygenase (COX) inhibitors

- to facilitate bladder filling and urine storage, 2703
- urethral function effects of, 1903

Cyclooxygenase-2 (COX-2), in UTUC, 2198

Cyclosporine, for BPS/IC oral therapy, 1241*t*, 1242–1243

CYP17 inhibition, 3693–3695, 3694*f*

Cyproheptadine, for delayed ejaculation, 1579

Cyproterone acetate, 3674

Cystadenomas, of testicular adnexa, 1709

Cystatin C, GFR estimation with, 1905

Cystectomy

- for cutaneous continent urinary diversion, 3206–3208, 3207*f*
- for non-muscle-invasive bladder cancer, 3106–3107, 3107*b*
- oncologic outcomes following, radical, 3118–3119
- partial, 3038–3043
  - evaluation for, 3038–3040
  - extraperitoneal approach to, 3040–3041
  - open, 3040
  - outcomes with, 3042–3043
  - surgical indications for, 3038–3040
  - surgical technique for, 3040–3041
  - transperitoneal approach to, 3041–3042, 3042*f*–3043*f*
- with pelvic lymph node dissection, radical
  - anatomic extent of, 3115–3116
  - bilateral, 3115
  - density of, 3117
  - distal urethra management, 3118
  - extracapsular nodal extension, 3117
  - intraoperative decision making, 3117–3118
  - intraoperative frozen sections of ureter, 3117–3118
  - managing female urethra in, 3118
  - for muscle-invasive bladder cancer, 3114–3119
  - number removed in, 3125
  - oncologic outcomes following, 3118–3119, 3118*t*

Cystic and solid renal masses, CT and, 48–50, 50*f*, 52*f*

Cystic dysplasia of rete testis, 899

Cystic fibrosis transmembrane conductance regulator, 1450

- mutation assessment, for male infertility, 1443

Cystic lymphangioma, retroperitoneal tumors and, 2237, 2237*f*

Cystic masses, retroperitoneal tumors and, 2236–2237

Cystic mesothelioma, retroperitoneal tumors and, 2238

Cystic nephroma, 765–766, 765*f*, 766*b*, 767*f*, 2129–2130, 2129*f*

Cystic partially differentiated nephroblastoma (CPDN), in pediatric patients, 1109

Cystic renal disease, 339, 349–350

Cystine stones, in renal calculi, 2029–2030, 2029*f*

Cystinuria, 859, 2029, 2060–2068, 2063*b*
  - ammonium acid urate stones, 2066
  - bladder calculi, medical management of, 2066–2067
  - clinical considerations of, 2060–2061
  - compliance and quality of life, 2062–2063
  - conservative strategies of, 2061
  - drug-containing calculi, 2065–2066, 2066*t*
  - follow-up of, 2062
  - infection calculi, 2063–2065, 2063*f*, 2064*t*, 2065*b*
  - medical therapy for, 2061–2062
  - metabolic stone formation, 2066
  - miscellaneous and drug-induced stones, 2065, 2065*b*

Cystitis
  - definition of, 1129
  - diminished bladder capacity and, 2671
  - mechanosensitive afferent sensitization with, 2508
  - spinal cord chemical changes with, 2507
  - with spinal cord injury, 2467

Cystitis cystica, 526
  - of bladder, 3082, 3082*f*

Cystitis glandularis, of bladder, 3082, 3082*f*

Cystocele, 2526, 2587, 2589*f*

Cystography
  - after modern staged repair of exstrophy, 548–549
  - of bladder injuries, 3055*f*–3056*f*

Cystolithotripsy
  EHL for, 241.e2
  laser, 244.e4
Cystometrogram (CMG), in urodynamic studies, 2556, 2557*f*
Cystometry, in urodynamic studies, 2556, 2557*f*
Cystoplasty
  reduction, for prune-belly syndrome, 592
  sigmoid, 694–695, 696*f*
Cystoscopy, 156, 2443, 2443*f*
  after modern staged repair of exstrophy, 548–549
  antimicrobial prophylaxis for, 1198
  of bladder tumor, 3078–3079
  in diagnostic of hematuria, 250–251
  for genitourinary tuberculosis diagnosis, 1313–1314, 1314*f*
  for non-muscle-invasive bladder cancer, 3096
    surveillance, 3108
  for partial cystectomy, 3038
  for pelvic floor disorder assessment, 2534
  in pubovaginal sling placement and fixation, 2838–2839
  in retropubic midurethral sling, 2853
  for sphincteric urinary incontinence, 2996–2997, 2997*f*
  for transurethral resection of bladder tumor, 3133
  for urothelial cancer, 3091
  for UTUC, 2190
Cystourethoscopy, 26, 26*t*
Cystourethrogram
  for benign prostatic hyperplasia, 3348
  for striated sphincter dyssynergia, 2611*f*
Cystourethroscopy
  for benign prostatic hyperplasia, 3348
  equipment for, 186–187, 186*t*, 188*f*–189*f*, 188*t*
  indications for, 185–186, 186*t*, 191*b*
  patient preparation for, 187–190, 189*t*

- special circumstances in
    - continent urinary diversions, 191
    - suprapubic cystostomy, 190–191
- technique for, 190, 190*f*
- for urethral diverticula, 2982, 2982*f*

Cysts
- of Gartner duct, urethral diverticula differentiated from, 2986, 2986*f*
- of prostate, on transrectal ultrasonography, 3493, 3493*f*
- of scrotal wall, excision of, 1844
- simple, 766–770, 770*b*
    - classification of, 768–770, 769*b*, 770*f*
    - clinical features of, 766
    - evaluation of, 768, 768*f*–769*f*
    - histopathology of, 766–768
    - prognosis of, 770, 770*f*
    - treatment of, 770, 770*f*
- of Skene gland, urethral diverticula differentiated from, 2974, 2986*f*
- vestibular, 976–977, 977*f*

Cytochrome P450 oxidoreductase deficiency, 1011

Cytokine regulation, 788

Cytokines, 1333–1334, 1335*f*, 1335*t*
- in benign prostatic hyperplasia, 3311, 3312*f*
- septic shock and, 1183
- in tubulointerstitial fibrosis, 787–788

Cytoreductive androgen deprivation therapy (ADT), for localized prostate cancer, 3524

Cytoreductive nephrectomy
- laparoscopic, 2298
- for metastatic RCC, 2325–2328, 2326*f*–2327*f*, 2327*t*, 2328*b*

Cytosine, 1346.e1, 1346.e2*f*

Cytosolic free calcium, 1495

Cytotoxic T-lymphocyte antigen-4 (CTLA-4), 2146

D

da Vinci robotic platform, 467

da Vinci Robotic System, 211, 212.e2*f*
  instrumentation for, 218, 218*f*
  virtual reality training for, 231.e2, 233.e1*f*

da Vinci Surgical System, 2822–2823

DA-8031, for PE, 1572.e2

Danish Prostatic Symptom Score (DAN-PSS), 110*t*, 3344

DAN-PSS, Danish Prostatic Symptom Score

Dantrolene, to facilitate bladder emptying, 2720.e3

Dapoxetine, and PE, 1571

Darifenacin hydrobromide, to facilitate bladder filling and urine storage, 2682*t*, 2684–2685

Darkfield examination, syphilis test, 1258

Dartos pouch procedure, 1855

Data Management and Coordinating Center (DMCC), 3478–3479

Davis and Trattner Diagnostic Foley catheters, 154

Daytime urinary incontinence, bladder dysfunction and, 655–660, 660*b*

DBD, Diabetes-induced bladder dysfunction

DDR, DNA damage response

De novo detrusor overactivity, as complication of anterior colporrhaphy, 2782

Debulking nephrectomy, for metastatic RCC, 2325–2328, 2326*f*–2327*f*, 2327*t*, 2328*b*

Decipher assay, 3488

Decipher biopsy test, 3542–3543

Decipher test, 3521

Decision making, in intraoperative consultation, 296–297, 297*f*

Decreased adrenal function disorders, 2380–2383, 2383*b*
  - clinical characteristics, 2381–2382, 2382*t*
  - diagnostic tests, 2382
  - overview and epidemiology, 2380–2381
  - pathophysiology, 2381, 2381*f*
  - prognosis, 2383
  - treatment, 2382–2383, 2383*t*

De-differentiated liposarcomas, in retroperitoneum, 2230

Deep brain stimulation, for Parkinson disease, 2606

Deep perineal space, 1807.e10

Deep venous thrombosis (DVT)
  - after laparoscopic and robotic surgery, 231
  - after retropubic radical prostatectomy, 3563
  - prophylaxis, after laparoscopic radical prostatectomy, 3579

Defecation disorders, 667–679, 667*b*
  - classification of, 667–671, 668*t*
  - disimpaction for, 672
  - epidemiology of, 667–671, 668*t*
  - evaluation of, 667–669, 668.e1*f*, 669*t*, 671*b*
  - imaging studies of, 669–671, 669*f*–670*f*, 669.e1*f*, 670.e1*f*
  - large bowel/rectum washout for, 672
  - maintenance therapy for, 672–673
  - management of, 671–678, 671*f*, 673*b*, 679*b*
  - nonpharmacologic interventions, 671–673
  - prognosis of, 673
  - surgical management of, 673–678, 673*f*
    - enema regimen for, 677–678, 678*f*
    - operative technique for, 674–677, 675*f*–677*f*
    - outcomes with, 678, 678*f*, 678*t*
    - patient selection and preparation for, 674
  - urinary tract and, 667, 668*f*

Deferential artery, 1370–1371, 1372*f*, 1375, 1393, 1394*f*

Definitive perineostomy, for transmen, 3072, 3072*f*

Deflazacort, for ureteral stone passage, 1900

Defunctionalized bladder, lower urinary tract dysfunction and, 2632–2633

Dehydroepiandrosterone (DHEA), 3281, 3283*f*

Delayed contrast reactions, in contrast media, 32

Delayed ejaculation, 1572–1579, 1579*b*

- causes of, 1574, 1574*t*
- and congenital disorders, 1575
- and endocrinopathy, 1575

Electrosurgery

- devices for laparoscopic and robotic surgery, 214
- safety of, 236–237
- tissue dissection and cauterization with, 235–237, 236*f*

Electrotonic spread, in ureteral cells, 1882

Elephantiasis, as filariasis clinical manifestation, 1330, 1330*f*

11p15 locus, in Wilms tumor, 1097*t*, 1098

Elocalcitol, to facilitate bladder filling and urine storage, 2713.e1

EM, Erythema multiforme

Embolization

- before kidney surgery, 2248, 2248.e1*f*
- of prostate, 3445–3446
- for renal injuries, 1986, 1986*f*
- for renal tumors, targeted, 2323

Embolotherapy, 903, 903.e1*f*

Embryology, 799–800, 801*b*

- of exstrophy-epispadias complex, 530, 530*f*
- of female genitalia, 973–974, 974*f*, 974*b*
- of neuroblastoma, 1087–1088
- of prune-belly syndrome, 581
- of supernumerary kidney, 721
- of testis, 949–953
- of thoracic kidney, 725–726
- of unilateral renal agenesis, 718, 719*f*
- of vagina, 973–974, 974*f*, 974*b*

Embryonal carcinoma (EC), histology of, 1682–1683, 1683*f*

Embryonal RMS, 1111, 1112*f*, 1113*b*

Embryonic testicular regression, 1005–1006

EMDA, Electromotive drug administration

Emergency situations, 118

EMG, Electromyography

Emphysema, subcutaneous, during laparoscopic and robotic surgery, 225

Emphysematous cystitis, 1158–1159

Emphysematous pyelonephritis, 1171–1172, 1171*f*

Empirical treatment, in male infertility, 1452

EMT, Epithelial-mesenchymal transition

En bloc hilar vessel stapling, in laparoscopic radical nephrectomy, 2297

Encephalitis, and ED, 1502

Endo Close, 219

Endo Stitch, 215

EndoAvitene, 215.e2

Endocarditis, antimicrobial prophylaxis for uncomplicated urologic procedures and, 1200

Endocrine, concepts of, basic, for HPG axis, 1390, 1391*f*

Endocrine-disrupting chemicals (EDCs), cryptorchidism and, 949

Endocrine evaluation, and male infertility, 1436–1438

Endocrinology, of prostate, 3280–3295, 3281*f*

- adrenal androgens, 3282–3283, 3283*f*
- androgen-binding proteins in plasma, 3282*f*, 3284
- androgen production by testes, 3281–3282, 3282*f*–3283*f*, 3282*t*
- estrogens in male, 3282*t*, 3283–3284

End-of-life care, 2922

Endometriosis, of bladder, 3039, 3040*f*

Endopelvic fascia, 2850
    incision of, in retropubic radical prostatectomy, 3552, 3552*f*
Endopyeloplasty, percutaneous, for ureteropelvic junction obstruction, 1949
Endopyelotomy, for ureteropelvic junction obstruction, 191–192
Endoscopic incision (direct vision internal urethrotomy), for transmen, 3071
Endoscopic inguinal lymphadenectomy, for penile cancer, 1794
Endoscopic surgery, 145
    complications, of seminal vesicle surgery, 1863
Endoscopy, 185–202
    of bladder diverticula, 2969, 2970*f*
        management of, 2972
    of cloacal anomalies, 1024–1025, 1025*f*
    equipment and video-endoscopic systems for, 185, 186*f*–187*f*
    female pelvis anatomy for, 2443, 2443*f*, 2443*b*
    in genitourinary tuberculosis treatment, 1317
    history of, 185
    kidney anatomy for, 1865.e2*f*
    for male urinary incontinence, 2543
    of ureteral anomalies, 799*f*–800*f*, 808, 808*f*–809*f*
    of urogenital sinus abnormalities, 1023*f*–1024*f*
Endothelial dysfunction, 1420
Endothelins (ETs)
    lower urinary tract and, 2502
    renal vascular tone control by, 1913
    urethral function effects of, 1903–1904
Endothelium, ED and, 1506
Endoureterotomy, for ureteral stricture disease, 1968–1969
    antegrade approach to, 1969
    combined retrograde and antegrade approach, 1969
    results with, 1969
    retrograde ureteroscopic approach to, 1968–1969, 1969*f*

Endourologic management
- of upper tract urothelial cancer, 2210–2224
  - antegrade nephroureteroscopic, 2212–2219, 2215*f*–2217*f*, 2218*t*
  - basic attributes, 2210–2211, 2210*f*
  - lymph node-positive and metastatic disease treatment, 2222–2224, 2223*f*
  - positive upper tract urinary cytology and carcinoma in situ management, 2219–2222, 2219*f*, 2221*f*, 2221*t*
  - retrograde ureteroscopic, 2211–2212, 2211*f*, 2213*f*, 2214*t*, 2215*f*
- for ureteral stricture disease, 1966–1969, 1971*b*
- for ureteroenteric anastomotic stricture, 1977, 1978*f*
- for ureteropelvic junction obstruction, 1947, 1952*b*

Endourology, rise of, 2069.e2–2069.e3

Endovascular stents, for renovascular injuries, 1990

EndoWrist instruments, 218, 218*f*

End-stage renal disease (ESRD)
- in children, 355–357
- in CKD, 1929–1930
- neural tube defects and, early intervention for, 629

Enema
- cleansing, for prostate biopsy, 3496
- for defecation disorders, 677–678, 678*f*

Energetic harmony, 2749

Energy modalities in urologic surgery, for tissue dissection and cauterization
- electrosurgery, 235–241, 236*f*
- ultrasound instrumentation, 237–238

Enhanced recovery after surgery (ERAS), 453–455, 3165–3169, 3167*t*–3168*t*, 3170*t*–3174*t*

Enteral nutrition, 122

Enteral tube feeds, 449

Enteric hyperoxaluria, 2022–2023, 2022*f*, 2056
- medical therapy for, 2057

Enterobiasis, of genitourinary tract, 1332

Enterocele, 2526, 2587, 2589*f*

Enterococcus, 442

Enterocystoplasty, 3034–3038

- complications with, 3036–3038
- evaluation for, 3034–3035
- laparoscopic and robotic techniques, 3036, 3037*f*
- outcomes with, 3037–3038
- postoperative care of, 3036–3038
- seromuscular, 705–706, 705*f*
- surgical indication of, 3034–3035
- surgical technique for, 3035–3036, 3035*f*

Enucleation, for small renal tumors, 2263, 2264*f*

Enuresis

- alarm for, 663–664
- alternative therapies for, 665
- background on, 660–661
- behavioral therapy for, 663, 664*f*
- combination therapy for, 665
- epidemiology of, 661, 661*f*
- evaluation of, 662–663
- genetics of, 661
- natural history of, 661, 661*f*
- nocturnal, 2539, 2581
- pathophysiology of, 661–662, 662*f*
- patient history of, 6
- pediatric, 660–665, 665*b*
- pharmacotherapy for, 664
- terminology for, 660–661
- treatment of, 663–664, 2547

Enuresis risoria, 658–660

Environmental factors, UTUC variations and, 2186–2188

Environmental pollution, bladder cancer and, 3077

Enzalutamide, 3676, 3695–3696, 3695*f*

Eosinophilic cystitis, 526, 526*f*

EP, Etoposide-cisplatin

EPD, Extramammary Paget disease

Ephedrine

- in stone formation, 2033
  - surgical management of, 2077.e2–2077.e3
- for stress urinary incontinence in women, 2714

Epidemiology of Lower Urinary Tract Symptoms (EpiLUTS) II, 2734

Epidermal growth factor receptor (EGFR) therapy, for metastatic bladder cancer, 3131

Epidermoid cysts, 1123, 1304, 1305*f*

- testicular, 1708

Epididymal appendix, 391–392, 392*f*

Epididymal cysts, 903

Epididymal tumor excision, 1850

Epididymal/vasal injury, complication of scrotal surgery, 1856

Epididymectomy, 1853

- for chronic scrotal pain syndrome, 1222

Epididymis, 319*f*, 1850

- acute, 1853
- anatomy of, 1376*b*
  - arterial supply, 1375
  - blood supply of, 1454, 1454*t*
  - gross structure, 1374, 1374*f*–1375*f*
  - innervation in, 1403
  - lymphatic supply, 1375
  - microanatomic architecture, 1374–1375
  - nerve supply, 1375
  - vascular and lymph supply, 1402–1403
  - venous drainage, 1375
- anomalies of, 903
  - cryptorchidism and, 962–963, 962*f*
- appendix, torsion of, 897–898
- chronic, 1853
- in genitourinary tuberculosis, 1309
- HIV and, 1266
- imaging of
  - magnetic resonance imaging, 1376
  - ultrasound, 1375–1376, 1376*f*
- palpable abnormalities of, 1853
- physiology of, 1402–1406, 1406*b*
  - cytoarchitecture, 1403–1404

        - gross architecture in, 1402–1403, 1403*f*
        - regulation of, 1405–1406

Epididymitis, 898–899
    - after photoselective vaporization of prostate, 3441
    - as STD, 1255

Epididymo-orchitis, 392, 410–411

Epidural cord compression, in castration-resistant prostate cancer, 3702, 3703*t*

Epigenetic anomalies, and male infertility, 1446

Epigenetic changes, male reproductive physiology and, age-related, 1402

Epigenetic events, in prostate cancer, 3470

Epigenetic modifications, as prostate cancer biomarkers, 3487–3489

Epispadias, 568–572, 572*b*, 1449
    - female, 570–572, 571*f*–572*f*
        - associated anomalies, 571
        - operative techniques for, 571, 573*f*
        - surgical objectives for, 571
        - surgical results for, 571–572
    - male, 568–570, 568*f*
        - associated anomalies, 568–569
        - genital reconstruction in, 569
        - surgical management of, 569–570
        - urethral reconstruction in, 569
        - urinary continence in, 569–570, 570*t*
    - repair of, 550–551
        - failure of, 564
        - outcomes and results with, 557–558

Epithelial cell receptivity, in UTIs
    - bladder cells, 1136–1137, 1137*f*
    - vaginal cells, 1135–1136, 1135*f*
    - variation in, 1136

Epithelial-mesenchymal transition (EMT), 789

Epithelial metaplasia, of bladder, 3081

Epithelial permeability, bladder glycosaminoglycan layer and, 1232.e5–1232.e7, 1232.e7*b*

Epithelial spread, of UTUC, 2194

Epithelial stem cells, of prostate, 3278*f*, 3279

Epithelium, epididymal, 1403–1404, 1403*f*

EPO, Erythropoietin

Epoöphoron, 319*f*

Epstein criteria, of localized prostate cancer, 3526–3527

EQUIL 2, 2010

ERAS, Enhanced recovery after surgery

Erbium:YAG (Er:YAG) laser lithotripsy, basic physics of, 244

Erectile bodies, of penis, 1807.e6*f*–1807.e7*f*

Erectile dysfunction (ED), 1425–1426

- after laparoscopic radical prostatectomy, 3579
- after photoselective vaporization of prostate, 3442
- after retropubic radical prostatectomy, 3564
- after robotic radical prostatectomy, 3582–3583, 3582*f*
- arteriogenic, 1504–1505
- cardiovascular disease and, 1425–1426, 1426*b*
- causes of
  - arteriogenic, 1505
  - cavernous (venogenic), 1505*t*
  - drug-induced, 1506–1509
- classification of, 1502*b*
- corporal structural defects and, 1505–1506
- endocrinologic, 1503–1504
- epidemiology of, 1513–1514
- evaluation and management of, 1513–1538
  - diagnostic evaluation, 1517–1519, 1518*f*
  - historical perspective, 1513, 1514*t*
  - management principles, 1515–1517, 1515*t*, 1516*f*
  - public health significance, 1513–1514
  - specialized evaluation and testing, 1519–1529, 1521*t*
  - treatment considerations, 1529–1538
- HIV and, 1267
- hormonal therapy and, 3681

intraoperative troubleshooting, 1588–1591, 1592*b*
    crural crossover, 1589–1591, 1590*f*
    fibrotic corpora, 1588–1589, 1589*f*
metabolic syndrome and, 1422
neurogenic, 1502–1503
pathophysiology of, 1500–1512, 1512*b*
    incidence and epidemiology of, 1500–1512
patient history of, 6, 8*t*
and PD, 1600–1601
perspectives on, 1512
postoperative complications of, 1591–1596, 1596*b*
    cylinder aneurysm as, 1593, 1593*f*
    cylinder erosion as, 1594, 1595*f*
    cylinder extrusion as, 1593–1594, 1594*f*–1595*f*
    infection as, 1591–1593, 1592*f*, 1593*b*
    penile necrosis after implant placement, 1595–1596, 1595*f*
    visceral erosion of the reservoir, 1594–1595, 1595*f*
preoperative preparation for, 1583–1584
    device placement for, 1585–1588, 1585*f*–1587*f*, 1588*b*
    incision for, 1584–1585, 1585*f*
    reservoir placement, 1586–1588, 1587*f*–1588*f*
primary, 1511–1512
prostate cancer and, 3606
psychogenic, 1501–1502
risk factors for, 1501, 1502*f*
surgery for, 1582–1598
    device placement for, 1585–1588, 1585*f*–1587*f*
    incision for, 1584–1585, 1585*f*
    informed consent for, 1582–1583, 1584*b*
    patient and partner satisfaction for, 1597–1598
    postoperative care for, 1596–1597
    in special situations, 1596
    types of implants for, 1582, 1583*f*
with transurethral vaporization of prostate, 3426
with urethral distraction injury, 3060
vascular, 1505
Erectile Dysfunction Inventory of Treatment Satisfaction, 111
Erectile prosthesis, testicular implants and, 3069, 3070*f*

Erector spinae, 1658, 1662*f*–1665*f*, 1664*t*

Ergot alkaloids, with RPF, 1978

Erlotinib, for RCC, 2343–2344

Erosion, in penile implant, 1594, 1595*f*

Erysipelas, 1288–1289

Erythema multiforme (EM), 1277–1278, 1278*f*

Erythromycin, in pregnancy, 1187*t*

Erythroplasia of Queyrat, 1742

Erythropoiesis, renal regulation of, 1914

Erythropoietin (EPO), 1914

Escherichia coli, 428, 429*f*

ESRD, End-stage renal disease

Established urinary incontinence, in geriatric patients, 2919

Estradiol, 1391, 1434, 1437

Estrogens, 1390, 1394

- benign prostatic hyperplasia role of, 3308–3309, 3308*t*
- bladder and, 2503
- continence mechanism and, 2713
- to facilitate bladder filling and urine storage, 2682*t*
- and female sexual response, 1627.e5
- in male, 3282*t*, 3283–3284
- for overactive bladder, 2709–2710
- in prostate cancer, 3462–3463
- for stress urinary incontinence in women, 2713–2714
- supplementation of, for vesicovaginal fistula surgery, 2934
- urethra and, 2503
- for urgency urinary incontinence, 2709–2710
- for UTIs, 1164–1165, 1164*f*

ESWL, Extracorporeal shock wave lithotripsy

ESWT, Extracorporeal shock wave therapy

Ethics, 115–118
  medical, 115–116
Ethnicity
  renal calculi and, 2006
  urinary incontinence and, 2583–2585
Etoposide-cisplatin (EP), for seminomas, 1705
ETs, Endothelins
ETS family gene fusions, 3469
European Cooperative Groups, bladder RMS treatment approaches of, 1115
Everolimus, for RCC, 2337, 2338*f*
Evicel, 215.e2
Ewing sarcoma, retroperitoneal tumors and, 2232–2233, 2233*f*
Ewing-like sarcoma, retroperitoneal tumors and, 2232–2233, 2233*f*
Excisional tapering, for megaureter in children, 851–852, 851*f*
Excitation-contraction coupling
  in detrusor muscle, 2474–2475, 2475*f*
  in ureters, 1884–1885
Excretory urography
  ureter anatomy on, 1873–1874

  of urinary tract obstruction, 780
Excurrent ducts, of testis, 1454
Exercise, for prostate cancer, 3543–3544
Exercise-induced hematuria, 18
Exogenous Cushing syndrome, 2361, 2365
Expressed prostatic secretions, 24, 25*f*
Exstrophy
  in perinatal urology, 379–382
  in transitional urology, 1049–1050

        - female with, 1051–1052
        - long-term reconstructive outcomes, 1049
        - urologic, 1049–1050
- Exstrophy-epispadias complex (EEC), 528–580, 529*f*, 531*b*
    - adolescents with, 565
    - adults with, 565
    - embryology of, 530, 530*f*
    - fertility with
        - female patient, 567
        - male patient, 566
    - historical aspects of, 528
    - incidence of, 528–530
    - inheritance of, 528–530
    - long-term adjustment issues with, 567–568, 568*b*
    - prenatal diagnosis of, 538, 538*b*
    - pseudoexstrophy, 537
    - quality of life with, 567
    - sexuality with
        - female concerns, 566–567
        - male concerns, 565–566
    - split symphysis variant of, 538
    - variants of, 537–538, 538*f*
- Extended-core biopsy techniques, 3497, 3498*f*
- Extended pelvic lymphadenectomy
    - common iliac, 3152, 3153*f*–3154*f*
    - external iliac, 3148–3149, 3151*f*
    - hypogastric, 3149–3152, 3153*f*
    - obturator, 3149, 3152*f*
    - presacral, 3152, 3154*f*
- Extended sentinel lymph node dissection, for penile cancer, 1760
- Extensively drug-resistant tuberculosis, 1318
- External beam hypofractionation, outcomes for, 3611–3612, 3611*t*, 3612*b*, 3613*t*
- External-beam radiation therapy, for penile cancer, 1765, 1766*t*
- External beam radiation treatment, for prostate cancer, 3593–3596, 3596*b*

    brachytherapy *versus*, 3612–3613, 3614*t*
    fractionation, 3593
    heavy particle beams/proton therapy, 3594–3596, 3594*f*, 3595*t*
    high dose rate as a boost with, 3599
    outcomes for, 3609–3610, 3610*t*
    radiobiologic basis for hypofractionation, 3593, 3593*t*
    stereotactic body radiation therapy, 3593–3594
    tumor control after, 3611*b*
External collecting devices, 2903–2904
External compression (Credé), 2902
External genitalia, 312*b*
    male, development of, 1392, 1392*f*
External iliac lymphadenectomy, 3148–3149, 3151*f*
External irradiation, brachytherapy combined with, 3599–3600
External sphincter
    damage, orthoptic urinary diversion and, 3238
    male sphincteric mechanisms and, 2594
    urodynamic studies of, 2568–2569
Extracellular matrix, in obstructive nephropathy, 788–790
Extracorporeal renal surgery (ECRS), 2254–2257, 2256*f*
    preoperative considerations for, 2254–2255
    surgical procedure for, 2255–2257
Extracorporeal shock wave lithotripsy (ESWL), 2094–2103, 2103*b*, 2115
    adjuncts to improve, 2102, 2102*b*
    bioeffects of, 2097–2100
        acute renal injury as, 2098–2099, 2098*f*–2099*f*, 2099*b*
        chronic renal injury as, 2099–2100, 2099*t*
        extrarenal damage as, 2097–2098, 2097*f*
    combination of ultrasonography and fluoroscopy for, 2095
    fluoroscopy for, 2094–2095
    future direction in, 2102–2103, 2103*f*
    generator types for, 2094
        electrohydraulic (spark gap), 2094, 2095*f*

    - electromagnetic, 2094, 2095*f*
    - piezoelectric, 2094, 2096*f*
  - imaging systems for, 2094–2095
  - methods and physical principles, 2094–2097
  - optimization of, 2100–2102, 2100*b*, 2101*f*, 2102*b*
  - stone fragmentation in, 2095–2097, 2096*f*
  - tissue injury from, 2100
  - ultrasonography for, 2095

Extracorporeal shock wave therapy (ESWT), and PD, 1614, 1617*t*

Extraction, in laser lithotripsy, 2111

Extragenital skin harvest, for hypospadias, 945

Extramammary Paget disease (EPD), as neoplastic condition, 1301–1302, 1301*f*

Extraperitoneal approach
  - anterior, to laparoscopic pyeloplasty, 1956
  - operative team placement for, 211

Extrapituitary endocrine modulators, 1448

Extraprostatic extension, 3507, 3511

Extratesticular endocrine dysfunction, male infertility and, 1448–1449

Extravaginal spermatic cord torsion, 897, 897*f*

Extravasation of contrast material, contrast media and, 32

Extrinsic apoptotic pathway, 1366.e1*f*–1366.e2*f*, 1366.e2

Extrusion, in penile implant, 1593–1594, 1594*f*–1595*f*

Eyeball UDS, 2534

Eye-of-the-needle technique, 166–167, 167*f*

F

F antigens, 428–429

FAAH, Fatty acid amide hydrolase

Fabry disease, 1302, 1303*f*

Facility setup, for urodynamic studies, 2552–2553

Factors, additional, in urodynamic studies, 2554

Failed epispadias repair, reconstructive surgery for, 1813

Failed hypospadias repair, reconstructive surgery for, 1812–1813

Fallopian tubes
- anatomy of, 2436–2437
- for continent urinary diversions, 709

Falls, nocturia and, 2666

Familial benign prostatic hyperplasia, 3311–3312, 3311*t*

Familial hypomagnesemia with hypercalciuria and nephrocalcinosis (FHHNC), 2019

Familial hypoplastic glomerulocystic kidney disease, 756–757

Familial papillary RCC, molecular genetics of, 1354*t*, 1358

Familial RCC, 2141–2145, 2142*t*–2143*t*, 2144*f*
- treatment of, 2173–2174, 2174*f*

Familial Wilms tumor, 1098

Family history, 9
- prostate cancer and, 3542

Fanconi syndrome, 348

Fascia lata, 2834
- harvest of, 2837

Fasciae
- of anterior abdominal wall, 2429*f*
- of lower abdominal wall, 2444, 2446*f*
- pelvic
  - female, 2427, 2429*f*
  - male, 2448*f*, 2449, 2452*f*
- of perineum and perineal body, 2449, 2450*f*

Fascial closure
- after laparoscopic and robotic surgery, 218–219

- techniques, 150–151

Fascial sling

- for bladder neck reconstruction, 686–687
- results with, 686–687
- technique for, 686

FAST, Focused assessment with sonography for trauma

Fast spin-echo (FSE), 412–413

Fast-twitch fibers, of urethral striated muscle, 2466

Fatty acid amide hydrolase (FAAH), 2713.e2

Febrile child, 426

Fecal diversion, for radiation fistula, 2956

Fecal impaction, transient urinary incontinence and, 2919.e1

Fecal incontinence (FI)

- in geriatric patients, 2920.e9
- ultrasound for, 2439, 2440*f*

Female circumcision, 987–988, 988*f*

Female external genitalia, 2435–2436, 2436*f*–2437*f*

- abnormalities of
  - acquired, 986–988
  - cervical atresia, 984–985, 985*f*
  - clitoris, 975, 977*b*
  - congenital, 975–986
  - lateral fusion, 985–986
  - management of, 973–989
  - structural, 974
  - vagina, 978–986, 982*b*
  - vertical fusion, 979–981
  - vestibule, 975–977, 977*b*
- acquired disorders of, 986–988, 988*b*
  - condyloma acuminatum, 988
  - female circumcision, 987–988, 988*f*
  - labial adhesions, 986–987, 987*f*
- defect of, in bladder exstrophy, 534–535, 535*f*
- development of, 307*f*, 310–311, 311*f*–313*f*

  - embryology of, 973–974, 974*f*, 974*b*
  - evaluation and classification of, 974, 975*f*

Female genital-pelvic pain dysfunction, 1636

Female orgasmic disorder, 1646, 1648*b*
  - assessment for, 1646–1647
  - with desire and arousal problem, 1647–1648
  - medical treatment for, 1647–1648
  - medication-induced, 1648
  - psychosocial treatment for, 1647
  - sexual enhancement products, 1647

Female pelvis
  - anatomy of, 2427–2443, 2439*b*
    - anal perineum of, 2435
    - bony pelvis, 2427, 2428*f*
    - external genitalia of, 2435–2436, 2436*f*–2437*f*
    - fascia of, 2427, 2429*f*
    - innervation of, 2433–2434
    - ligaments of, 2428–2430, 2430*f*–2432*f*
    - lymphatic drainage of, 2433, 2434*f*
    - muscles of pelvic floor, 2430–2432, 2432*f*
    - organ support of, 2438, 2438*f*
    - organs of, 2436–2438, 2437*f*
    - perineum of, 2434–2435, 2435*f*
    - peritoneum of, 2427, 2429*f*
    - urethra, 2438–2439, 2439*f*, 2465–2466, 2466*f*
    - vasculature of, 2432–2433, 2433*f*
  - endoscopic anatomy of, 2443, 2443*f*, 2443*b*
  - radiographic anatomy of, 2439–2443
    - fluoroscopy, 2442–2443, 2442*f*
    - magnetic resonance imaging, 2440–2442, 2440*f*–2442*f*
    - ultrasound, 2439, 2440*f*

Female persistent genital arousal disorders, 1650, 1650*t*
  - psychosocial characterization and etiologic factors, 1650
  - treatment targets for, 1650

Female radical cystectomy, 3155–3157, 3157*f*–3158*f*

Female reproductive system, pediatric tumors of, 1121*b*
  - cervical or uterine RMS, 1120

    - ovarian, 1120–1121
    - vaginal RMS, 1119–1120, 1119*f*
    - vulvar RMS, 1119
- Female reproductive tract, development of, 324–327, 324*f*–325*f*
- Female sexual arousal disorders, 1648–1649, 1651*b*
    - interview assessment for, 1649, 1649*t*
    - pharmacotherapy for, 1649–1650
        - hormonal therapy, 1649–1650
        - nonhormonal therapy, 1650
    - potential treatments for, 1649
- Female sexual arousal dysfunction, 1636
- Female sexual dysfunction
    - epidemiology of, 1636–1637, 1637*b*
    - lower urinary tract dysfunction and, 1654–1655, 1657*b*
        - clinical signs and investigations for, 1655
        - epidemiology of, 1654
        - etiology and classification of, 1654–1655
        - links and treatments, 1655–1657
        - self-image/body image connected to, 1657
        - sexual lifestyle and communication and, 1654–1655, 1654*t*
- Female Sexual Function Inventory (FSFI), 112, 112*t*
- Female sexual interest-arousal disorders, 1635–1636
- Female sexual interest disorder, 1640–1648, 1646*b*
    - definition of, 1640–1641
    - evaluation of, 1641–1643, 1642*t*–1643*t*
    - pathophysiology of, 1641, 1641*f*
    - treatment for, 1643, 1644*f*
        - medical, 1643–1646
        - psychological, 1643
- Female sexual organs, anatomy and physiology of, 1627, 1627*b*
- Female sexual response
    - hormonal regulators of, 1627.e5–1627.e6
    - neurogenic mediators of, 1627.e5
- Female stress urinary incontinence, use of injectable agents for, 2890–2891

Female urethra, 152
- catheterization of, 153

Female urethral cancer, 1782–1785, 1785*b*
- anatomy and pathology of, 1782–1785, 1783*f*
- epidemiology, etiology, and clinical presentation of, 1782
- evaluation and staging of, 1783
- prognosis of, 1783–1784
- recurrence after cystectomy, 1787–1789, 1789*b*
- treatment of, 1784–1785

Females, with exstrophy, 1051–1052
- fertility, 1051
- pregnancy and delivery, 1051–1052
- procedentia repair, 1051
- reconstruction of genitalia, 1051
- sexual function, 1051

Female-to-male transexuals, Transmen

Female-to-male transgender, reconstructive surgery for, 1841–1842, 1842*b*

Femoral nerve, 2453*t*

Fenretinide, for neuroblastoma, 1096

FEPs, Fibroepithelial polyps

Fertility
- after RPLND, 1729
- with cryptorchidism, 969–970
- with exstrophy-epispadias complex
  - female patient, 567
  - male patient, 566
- in prune-belly syndrome, 600
- RMS treatment effects on, 1116–1117
- sperm, 1405, 1405*f*
- urologic surgery and, 288
- Wilms tumor treatment effects on, 1108

Fesoterodine

  - for diminished bladder, 2675, 2675*t*–2677*t*
  - to facilitate bladder filling and urine storage, 2682*t*, 2685–2687
  - for urinary incontinence, in geriatric patients, 2920.e4

Fetal cystoscopy, in urinary tract dilation, 364–365

Fetal magnetic resonance imaging, 358, 359*f*

Fetal myelomeningocele closure, outcomes for, 382

α-Fetoprotein (AFP), in pediatric patients, 1122, 1122*f*

Fetus, fundamentals of, 404
  - MRI in, 412–413

Fever
  - evaluation and management of, 426–433, 427*f*
  - patient history of, 7
  - UTI diagnosis and, 1143

^{18}F-FACBC, 99

F-FDG PET/CT, 43

FFP, Fresh frozen plasma

FG, Fournier gangrene

FGF, Fibroblast growth factors

FH gene, systemic therapy targeting, 2343

FHHNC, Familial hypomagnesemia with hypercalciuria and nephrocalcinosis

FI, Fecal incontinence

Fibrin-based glue, for laparoscopic and robotic surgery, 215.e2

Fibrin sealants, 148

Fibroblast growth factor receptor therapy, for metastatic bladder cancer, 3131

Fibroblast growth factors (FGF), in prostate development, 3276

Fibroblasts, in tubulointerstitial fibrosis, 782*f*, 789

Fibrocystin, 748

Fibroepithelial polyps (FEPs), 526

- of ureter, 821–822, 821*f*–822*f*
- of urethra, 1776

Fibrosis
- mechanisms of, 788–790
- in obstructive nephropathy, 788–790
- PC-RPLND findings of, survival outcomes associated with, 1726, 1727*t*
- pelvic, as laparoscopic and robotic surgery contraindication, 203

Fibrotic corpora, 1588–1589, 1589*f*

Fibrotic gene expression, and PD, 1606

Fibrous dysplasia, 1933–1934, 1934*f*

Filariasis, of genitourinary tract, 1328–1331, 1332*b*
- diagnosis, 1330
- epidemiology, 1328–1329
- organisms, 1328, 1328*f*
- pathology and clinical manifestations, 1329–1330, 1329*f*–1330*f*
- prevention and control, 1331
- treatment, 1330–1331

Filling cystometry, for benign prostatic hyperplasia, 3347

Filtrate transport, 1906–1913
- acid-base balance, 1911–1912, 1912*f*, 1912*b*
- calcium, 1911, 1912*f*
- potassium, 1909–1910, 1910*b*
- sodium, 1906–1909, 1907*f*–1910*f*, 1909*b*
- solutes, 1912–1913
- water, 1910–1911, 1911*f*, 1911*b*

Fimbria, 319*f*, 324*f*

Finasteride
- for benign prostatic hyperplasia, 3371–3374, 3373*t*
- for diminished bladder, 2674, 2675*t*–2677*t*

Fine-needle aspiration cytology, for penile cancer, 1760

FIRSTANA trial, 3693

First-morning void, 2667

FISH, Fluorescence in situ hybridization

Fistula obstruction, 3272

Fistulae

- classification of, 2930–2931, 2931*f*
- complex, of posterior urethra, 1835–1836, 1836*b*
- cutaneous, 2962
- with intestinal anastomoses, 3179–3180
- other urinary, 2962, 2962*b*
- radiation, 2960–2962
  - chemotherapy of, 2961–2962
  - combination therapies of, 2962
  - diversion procedures for, 2961
  - interpositional grafts for, 2961
  - management approaches for, 2961
  - recommendations for, 2961
  - repair techniques for, 2961
- urethral, 883, 883*f*
- urethrocutaneous, 935–937, 936*f*–937*f*
- urinary tract, 2924–2963, 2924*b*
  - after renal preservation surgery, 2962
  - after renal transplantation, 2962
  - general considerations of, 2924
  - management of, 2925*b*
  - other, 2962, 2962*b*
  - surgical repair of, 2925*b*
- urocutaneous, 2962
- uroenteric, 2952–2953
  - pyeloenteric, 2953–2955, 2953*f*
  - vesicoenteric, 2953*t*
- urogynecologic, 2946
  - ureterovaginal, 2942, 2942*b*
  - urethrovaginal, 2947–2951
  - vesicouterine, 2946–2947, 2947*b*
  - vesicovaginal, 2924–2926
- urovascular, 2958
  - pyelovascular, 2958
  - renovascular, 2958
  - ureterovascular, 2958–2959

Fixed drug eruption, as papulosquamous disorder, 1282, 1283*f*

Fixed particle growth theory, 2011

FLA, Focal laser ablation

Flank approaches

- for open kidney surgery, 2249–2251
  - subcostal, 2249–2250, 2249.e1*f*, 2250*f*–2251*f*, 2250.e1*f*
  - supracostal, 2250–2251, 2251.e1*f*
- to ureteropelvic junction obstruction in children, 829

Flank incision, kidney and retroperitoneum approaches, 138–140

- 12th rib supracostal and 11th rib transcostal, 140, 140*f*
- true flank incision, 139–140, 140*f*

Flank muscles, of posterior abdominal wall, 1658, 1662*f*–1664*f*, 1664*t*

Flank pain, 400

- UTI diagnosis and, 1143

Flank retroperitoneal approach, in open adrenalectomy, 2410–2411, 2410*f*–2411*f*

Flap urethroplasty, for transmen, 3071

Flaps

- for continent urinary diversions, 707–709, *see also* specific flaps
- for penile transplantation, 1838–1842, 1840*f*, 1842*b*
- for ureteropelvic junction obstruction, 1960–1962
  - Culp-DeWeerd spiral flap, 1960–1961, 1961*f*
  - Foley Y-V plasty, 1960, 1960*f*
  - intubated ureterotomy, 1961–1962, 1963*f*
  - salvage procedures, 1963
  - Scardino-Prince vertical flap, 1961, 1962*f*
- for urethral and penile reconstruction, 1807, 1807*f*
  - axial, 1807, 1807*f*–1808*f*
  - island, 1807
  - peninsular, 1807
  - random, 1807, 1807*f*
- for urethral stricture disease, 1823–1827, 1824*f*–1825*f*

Flavoxate hydrochloride, to facilitate bladder filling and urine storage, 2682*t*, 2696

Flexible cystourethroscopes, 186–187, 189*t*

Flexible laser lithotripsy, 244.e4

Flexible lithotripters, 2109–2111

Flexible ureteroscopes, 194*f*–195*f*, 195, 196*t*

- care and sterilization of, 195–197, 197*f*
- technique, 201

Flibanserin, for female sexual interest disorder, 1645–1646

Flip-flap technique (Mathieu), 924, 924*f*

FloSeal, 148, 215.e2

- for renal trauma, 1990, 1990*f*

FLS, Fundamentals of Laparoscopic Surgery

Fluid intake, for pediatric kidney stone disease, 868–869

Fluids

- bladder cancer and, 3077
- intake of, renal calculi and, 2009
- management of, 2732–2733
  - evidence for, 2733
  - excessive, 2732–2733
  - inadequate, 2733
  - timing of, 2733

Fluorescence in situ hybridization (FISH), of bladder tumor, 3079

Fluorine-18 (^{18}F), 91

(^{18}F)fluoro-D-glucose (18F-FDG), 96, 97*f*, 100*b*

- for bladder cancer, 97
- for kidney cancer, 97–98
- for penile cancer, 100
- for prostate cancer, 98–100
- for testis cancer, 100

Fluoroquinolones

- prophylaxis with
  - for cystourethroscopy, 189
  - for uncomplicated urologic procedures, 1194*t*–1196*t*
- for UTIs, 1151*t*–1153*t*, 1153–1154, 1156, 1187*t*

Fluoroscopic-guided access, 166–169, 166*f*–167*f*

Fluoroscopic imaging, for urodynamics, 2535

Fluoroscopy, 389
  - of female pelvis, 2442–2443, 2442*f*
  - of male pelvis, 2457–2458
  - of pediatric stone disease, 861
  - ureteroscopy, 199

5-Fluorouracil
  - for condylomata acuminata, 1742.e3
  - for penile cancer, 1770

Flurbiprofen, to facilitate bladder filling and urine storage, 2682*t*, 2703

Flush stoma, 3182–3183

Flutamide
  - for benign prostatic hyperplasia, 3376–3377
  - for prostate cancer, 3674

Focal ablative therapy, for locally advanced prostate cancer, 3655
  - cryoablation, 3655
  - high-intensity focused ultrasound, 3655

Focal extraprostatic extension, 3511

Focal laser ablation (FLA), 3628, 3633*f*, 3634*t*, 3635*f*

Focal segmental glomerulosclerosis (FSGS), 345

Focal therapy, for prostate cancer, 3616–3639, 3639*b*
  - ablation patterns and current technologies of, 3624–3638
    - ablation approach, 3624
    - ablation types, 3624, 3624*f*
    - adjuvants to, 3638
    - brachytherapy, 3632–3638
    - cryotherapy, 3624–3628, 3625*f*, 3627*t*
    - follow up, 3638
    - high-intensity focused ultrasonography, 3628, 3629*t*–3630*t*, 3631*f*–3632*f*
    - irreversible electroporation, 3628–3632, 3635*f*, 3636*t*
    - laser, 3628, 3633*f*, 3634*t*, 3635*f*
    - other modalities, 3638
    - vascular-targeted photodynamic therapy, 3632, 3637*t*

- advanced imaging techniques in, 3621–3622
  - MRI-targeted/fusion biopsy, 3622
  - multiparametric magnetic resonance imaging, 3621–3622
- biologic basis for, 3616–3620
  - multifocality of, *versus* index lesion hypothesis, 3617–3620, 3619*t*, 3620*f*
  - using cancer grade as indication of aggressiveness, 3616–3617, 3617*f*
- clinical applications of, 3620
  - complementary roles and active surveillance, 3620
  - index lesion treatment, 3620
- concepts of, 3616
- future research for, 3638–3639
- historical perspective of, 3616
- patient selection for, 3620–3621
  - biopsy-based lesion identification, 3621
- promising imaging modalities of, 3622–3624
  - contemporary patient selection criteria, 3622–3624, 3623*t*
  - multiparametric ultrasonography, 3622
  - positron emission tomography, 3622

Focused assessment with sonography for trauma (FAST), of upper urinary tract, 1066

Focused ultrasound, for renal tumor ablation, 2319–2321

Folded rectosigmoid bladder, 3209

Foley catheters, 173, 484

Foley Y-V plasty, for ureteropelvic junction obstruction, 1960, 1960*f*

Follicle cells, 319*f*

Follicle-stimulating hormone (FSH), 1390, 1391*f*, 1437

Folliculitis, 1290–1291, 1291*f*

Foods, bladder cancer and, 3078

Force-length relations, of ureters, 1890, 1890*f*

Force-velocity relations, of ureters, 1890–1891, 1891*f*

Foregut, 318*f*

Foreign-body removal, bladder, 3043–3046
- complications of, 3046

    evaluation of, 3043–3044
    laparoscopic and robotic technique, 3044–3045, 3045*f*–3046*f*
    open technique of, 3044, 3045*f*
    percutaneous, 3045–3046
    postoperative care of, 3046
    surgical indication of, 3043–3044
    surgical technique of, 3044–3046

Formation product (K_f), 2009

46,XX DSD, 1007–1011

46,XX males, 1000–1001

46,XY complete, 998*t*, 1004–1005, 1005*f*

46,XY DSD, 1011–1017

Fosfomycin, for UTIs, 1151*t*–1153*t*, 1153

Fosfomycin trometamol, for UTIs, 1156

Fossa navicularis, 1383, 1383*f*–1384*f*, 1807.e2*f*, 1807.e4*f*, 1807.e8

Four-Box framework, 116, 117*t*

Fourchette, 1627.e2

Fournier gangrene (FG), 1289–1290, 1290*f*
    genital skin loss and, 3053

Four-principles framework, 115

Four-way catheter, 154*f*

Fowler syndrome, 2629, 2720.e3

Fowler-Stephens orchidopexy, 967–968

fPSA, Free prostate-specific antigen

12-Fr Cope nephrostomy tube, 181, 181*f*

Fractional excretion of sodium (FENa), urinary tract obstruction and, 777

Fractionation, in radiation therapy, 3593

Fracture

  of penis, 3048–3049, 3048.e1*f*, 3049*f*–3050*f*, 3049.e1*f*
  of testis, 3051–3053

Fragmentation, in laser lithotripsy, 2111

Frailty, 2913–2914, 2913*f*
  definition of, 108

Frank hematuria, 247

Frasier syndrome, 998*t*, 1004

Free crystal particle growth, 2011

Free graft urethroplasty, for transmen, 3071

Free prostate-specific antigen (fPSA), 3481–3482, 3481*t*, 3482*f*, 3517–3518
  isoforms, 3483–3484, 3483*f*

Free water loss, 341–342

Frequency-volume chart, 2666
  for benign prostatic hyperplasia, 3344–3345
  nocturia classification with, 2667, 2668*t*

Frequently-relapsing nephrotic syndrome (FRNS), 345

Fresh frozen plasma (FFP), transfusion with, 147

Fresh prostatic cancer tissues, genomic research on, 3586

FRNS, Frequently-relapsing nephrotic syndrome

Fructose, in prostatic secretions, 3295–3296

FSE, Fast spin-echo

FSFI, Female Sexual Function Inventory

FSGS, Focal segmental glomerulosclerosis

FSH, Follicle-stimulating hormone

Fuhrman's classification system, for RCC, 2148, 2148*t*

Full-thickness skin grafts, for urethral and penile reconstruction, 1805, 1806*f*

Functional acute kidney injury, in children, 353

Functional capacity, 120

Functional imaging
  in adrenal mass evaluation, 2396–2397
  of pheochromocytoma, 2375–2376, 2376*f*
Functional incidental training, in toileting programs, 2730.e1*t*
Functional incontinence, patient history of, 6
Functional phase. of dynamic renal imaging, 93
Functional profile length, 2563
Functional status
  assessment of, 107
  definition of, 106–107
Fundamentals of Laparoscopic Surgery (FLS), 471
Funguria, 445
Funiculoepididymitis, as filariasis clinical manifestation, 1329
Furosemide
  for nocturnal polyuria, 2673*t*
  in stone formation, 2033
Furunculosis, 1291, 1291*f*
Fusion anomalies, genitourinary trauma and, 1076, 1077*f*
Future business plan, for men's health center, 1427

G

G_1/S checkpoint, deregulation of, in GU cancers, 1347.e2
G2M checkpoint, deregulation of, 1347.e2–1347.e3
Gabapentin, to facilitate bladder filling and urine storage, 2713.e3
^{67}Ga-citrate, 96
Gadolinium, for contrast media, 34
Gadolinium-based contrast media (GBCM), contrast media and, 32–33
Galdakao-modified supine position, 165

Gallium-68 (^{68}Ga), 91, 92*t*

Ganglioneuroblastomas, in retroperitoneum, 2234, 2235*f*

Ganglioneuroma
  as benign lesion, 2392–2393, 2393*b*
  in retroperitoneum, 2234

GAP, Glans approximation procedure

^{68}Ga-PSMA PET scans, 3667

Gardasil, 1262

Gartner duct cysts, 319*f*, 977, 977*f*
  urethral diverticula differentiated from, 2986, 2986*f*

GAS, Gender-affirmation surgery

Gas embolism
  during laparoscopic and robotic surgery, 224–225
  vena caval thrombectomy causing, 2277

Gasless laparoscopic transperitoneal approach, 2416–2417, 2417*f*

Gastric contents, aspiration of, during laparoscopic and robotic surgery, 228.e1

Gastric pouch, for cutaneous continent urinary diversion, 3225–3226, 3225*f*–3226*f*

Gastrocystoplasty, 695

Gastroenterologic changes, with aging, 2906

Gastrointestinal cystoplasty, alternatives to, 702–706, 706*b*
  autoaugmentation, 703–705, 704*f*
  bladder regeneration, 706
  seromuscular enterocystoplasty, 705–706, 705*f*
  ureterocystoplasty, 703, 703*f*

Gastrointestinal injury
  during laparoscopic and robotic surgery, 225–226
  laparoscopic kidney surgery causing, 2307, 2307*f*
  during radical nephrectomy, 2261

Gastrointestinal tract

    abnormalities of, with cloacal exstrophy, 575
    after augmentation cystoplasty, 696–697
    in prune-belly syndrome, 587–588, 587*f*

Gastrointestinal viscera, in retroperitoneum, 1668–1669, 1668.e2*f*, 1669*f*–1670*f*, 1674*b*

Gastroparesis, lower urinary tract dysfunction and, 2630

GBCM, Gadolinium-based contrast media

GBS, Guillain-Barré syndrome

GC, Genomic classifier

GCTs, Germ cell tumors

GD, Gender dysphoria

GEARS, Global Evaluative Assessment of Robotic Skills

GelPort, 212, 212*f*

Gemcitabine, for non-muscle-invasive bladder cancer, 3105

Gender
    assignment of
        for cloacal exstrophy, 576–577, 577*f*
        in newborn, 1000
    desmopressin and, 2712
    lower urinary tract dysfunction and, 652
    renal calculi and, 2005–2006
    UTUC variations and, 2185

Gender-affirmation surgery (GAS), 3062

Gender dysphoria (GD), 3062

Gender identity, 3062
    role, and orientation, 996–997

Gender nonconforming youths, urologic issues in, 3062

Gender reassignment surgery (GRS), 3062

Gene amplification, androgen receptor and, 3685–3686

Gene fusions, in prostate cancer, 3468–3470 as biomarkers for, 3486

Gene rearrangements

  in prostate cancer, 1352–1353, 1354*t*

  in renal cancer, 1353, 1354*t*

  in testicular cancer, 1353

General anesthesia

  for laparoscopic and robotic surgery, complications related to, 228

  in urologic surgery, 132

General appearance, physical examination for, 9–10

Genes

  oncogenes, 1346–1347, 1347*b*

  structure of, 1346.e4

  tumor suppressor, 1346–1347, 1347*f*, 1347*b*

Genetic factors, in pelvic organ prolapse, 2591

Genetic mutations, male reproductive physiology and, age-related, 1402

Genetic predisposition, UTUC variations and, 2185, 2186*f*

Genetic syndromes, male infertility and, 1445–1446

Genetic testing, for evaluation of pediatric stone disease, 351

Genetics

  of autosomal dominant polycystic kidney disease, 750–751

  of autosomal recessive polycystic kidney disease, 748

  of benign prostatic hyperplasia, 3311–3312, 3311*t*

  of bladder tumor, 3076

  in BPS/IC etiology, 1232.e10

  of clear cell RCC, 2141–2143, 2143*t*, 2144*f*

  of enuresis, 661

  of hernia and hydroceles, 889

  of juvenile nephronophthisis, 755

  of lower urinary tract function, 2528

  of neuroblastoma, 1096–1099

  overview of, 741

  of prune-belly syndrome, 581

  - of tuberous sclerosis complex, 757, 759*f*

Genital bite wounds, 1293, 1294*f*

Genital burns, 3054

Genital lymphedema, 884–885

Genital Perception Score (GPS), 942–943

Genital ridges, 318*f*

Genital ulcers
  - noninfectious, 1286–1288, 1286*b*
    - aphthous ulcers and Behçet disease, 1286–1287, 1287*f*
    - pyoderma gangrenosum, 1287–1288, 1288*f*
    - traumatic causes, 1288, 1288*f*
  - STDs, 1255–1261, 1255*t*
    - chancroid, 1255*t*, 1259–1260, 1259*f*
    - diagnosis of, 1256
    - granuloma inguinale, 1260
    - herpes, 1255*t*
    - HPV, 1261, 1262*f*
    - lymphogranuloma, 1255*t*, 1260–1261, 1260*f*
    - *Molluscum contagiosum*, 1261, 1261*f*
    - pediculosis pubis, 1271
    - presentation of, 1256, 1256*f*
    - scabies, 1271
    - syphilis, 1255*t*, 1257, 1257*f*–1258*f*, 1257*t*
    - treatment of, 1256–1257, 1256*t*
    - vaginitis, 1271–1272, 1272*t*

Genitalia
  - ambiguous, 998–1018, 999*f*, 999*b*
  - external, development of, 305–310, 307*f*–310*f*, 312*f*
    - masculinization of, 305

Genitalia of female, external, 395–398
  - bladder and bowel dysfunction, 397–398
  - development of, 307*f*, 310–311, 311*f*–313*f*
  - foreign body, 398
  - hymenal disorders, 395, 396*f*
  - hymenal skin tags, 395
  - interlabial masses, 395

  - labial adhesions, 395, 396*f*
  - paraurethral cyst, 395, 397*f*
  - prolapsing ureterocele, 395, 397*f*
  - urethral prolapse, 395, 397*f*
  - vaginal discharge, 397
  - vaginal rhabdomyosarcoma, 397
- Genitalia of male, external, 391–395
  - abnormal penile orientation, 394
    - hypospadias, 394
    - parameatal urethral cyst, 394
    - penile curvature, 394
    - penile torsion, 394
    - priapism, 394–395
  - penile conditions, 393–395
    - buried penis, 394
    - circumcision, 393
    - concealed penis, 394
    - foreskin, 393
    - inconspicuous penis, 394
    - paraphimosis, 393
    - phimosis, 393
    - smegma pearl, 393–394
    - smegmoma, 393–394, 393*f*
    - webbed penis, 394
  - scrotal conditions, 391–393
    - epididymo-orchitis, 392
    - hernia, 392
    - hydrocele, 392
    - scrotal and testicular pain, 391
    - scrotal mass, 392
    - testicular torsion, 391
    - testicular tumor, 392–393
    - torsion of testicular, 391–392
    - undescended testicle, 391
    - varicocele, 392
- Genitocerebral evoked potential, 1527
- Genitofemoral nerve, 1372–1373, 2447*f*–2448*f*, 2453, 2453*t*
- Genitography, 390
- Genito-pelvic pain-penetration disorder, 1636, 1651–1653, 1653*b*

  - clinical presentation of, 1652, 1652*f*
  - clitoris and clitorodynia, 1651–1652
  - pain and sex, 1651
  - provoked vestibulodynia, 1651
  - treatment for, 1653

- Genitourinary malignancies, 1940–1941, 1941*b*
  - bladder cancer, 1941
  - molecular imaging of, 96–100
  - prostate cancer, 1941
  - renal cell carcinoma, 1940–1941, 1940*f*
- Genitourinary problem index (GUPI), 1211, 1212*f*
- Genitourinary region, pediatric, 391–402
  - external
    - of female, 395–398
    - of male, 391–395
  - sexual abuse, 398, 400
  - urinary tract, 398–402
    - infection of, 398–399, 402*b*
    - pyelonephritis, 398–399
    - urinary incontinence, 399–400
    - vesicoureteral reflux, 399
- Genitourinary surgery, genito-pelvic pain-penetration disorder and, 1652–1653
- Genitourinary tract
  - abnormalities of, with cloacal exstrophy, 575
  - embryology of, 305–340, 306*f*–307*f*
    - external genitalia, development of, 305–310, 307*f*–310*f*
    - female external genitalia, 307*f*, 310–311, 311*f*–313*f*
    - gonads, development of, 317–322, 318*f*
    - human seminal vesicle, development of, 317
    - kidneys, 333–340, 333*f*–334*f*, 339*b*
    - Müllerian structures, 322–329, 323*f*, 327*b*
    - ureter, development of, 329–333, 332*f*, 332*t*
- Genitourinary trauma
  - genitourinary malignancies, 2920
  - in geriatric patients, 2920.e11
- Genitourinary tuberculosis (GUTB), 1307–1319

- clinical manifestations and pathologic features of, 1308–1309
    - bladder, 1309
    - epididymis, vas deferens, testes, and scrotum, 1309
    - kidney, 1308–1309
    - prostate and seminal vesicles, 1309
    - ureter, 1309
    - urethra and penis, 1309
- development of, 1308
- diagnosis of, 1309–1314
    - culture, 1310
    - histopathology, 1310
    - nucleic acid amplification tests, 1310
    - radiography, 1311–1313, 1311*f*–1313*f*
    - screening tests, 1310–1311
- management, in special situations, 1318–1319
- relapse, 1318
- transmission and host immune response, 1307–1308
- treatment of, 1315–1318
    - medical therapy, 1311*t*, 1315–1317, 1315*t*–1316*t*
    - surgical therapy, 1317–1318

Genome, GU cancer alterations in, 1351–1362, 1362*b*
- bladder cancer, 1358–1360
- bladder RMS, 1111–1113
- CNAs, 1354, 1354*t*–1355*t*
- gross chromosomal abnormalities, 1351–1352, 1352*b*
- prostate cancer, 1352–1353, 1354*t*, 1355*f*
- renal cancer, 1353, 1354*t*, 1358
- testicular cancer, 1121, 1353, 1361–1362
- Wilms tumor, 1096–1099, 1097*t*, 1354*t*

Genomic assessment, in male infertility, 1442–1443

Genomic classifier (GC), of prostate cancer, 3542–3543

Genomic expression profiles, as prostate cancer biomarkers, 3488

Genomic predictors, hormonal therapy and, 3680

Genomic prostate score (GPS), 3543

Genomic sequence assessment, for male infertility, 1443

Genomic tests, for localized prostate cancer, 3529

Geography

- renal calculi and, 2006–2007, 2007*f*
- in transitional urology, 1047

Geriatric patients, in urinary incontinence, 2917–2920

- absorbent products for, 2920.e6
- behavioral therapies for, 2920.e3
- clinical evaluation of, 2920
- costs of, 2918
- established, 2919
- history for, 2920.e1
- laboratory testing for, 2920.e2
- negative impacts of, 2918–2919
- pharmacotherapies for, 2920.e3–2920.e4
- physical examination for, 2920.e1
- PVR assessment, 2920.e1
- risk factors of, 2918
- surgical therapies for, 2920.e4–2920.e6
- transient, 2919
- treatment of, 2920
- urine containment for, 2920.e6
- urodynamic studies for, 2920.e2
- voiding diaries, 2920.e1–2920.e2

Geriatric syndromes, 2913–2917

- asymptomatic bacteriuria, 2920.e10–2920.e11
- bladder outlet obstruction, 2920.e7
- delirium, 2914
- falls, 2915
- fecal incontinence, 2920.e9
- frailty, 2913–2914, 2913*f*
- genitourinary malignancies, 2920
- genitourinary trauma, 2920.e11
- hematuria, 2920.e11
- medication optimization, 2915–2917, 2916*t*–2917*t*

- neurogenic bladder, 2920.e7–2920.e8
- nocturia, 2920.e8–2920.e9
- pelvic organ prolapse, 2920.e9–2920.e10
- polypharmacy, 2915–2917
- pressure ulcers, 2915
- underactive bladder, 2920.e7–2920.e8
- urinary incontinence, 2917–2920
- urinary retention, 2920.e7–2920.e8
- urinary tract infections, 2920.e10–2920.e11

Geriatric urology patient
- care coordination of, 2921
- clinical evaluation of, 2908–2922, 2909*f*
  - activities of daily living, 2909
  - cognition of, 2910, 2911*f*
  - comprehensive geriatric assessment, 2913
  - depression in, 2910
  - functional assessment, 2909–2910
  - instrumental activities of daily living, 2909
  - mobility of, 2909–2910
- discharge planning for, 2921
- end-of-life care, 2922
- palliative care of, 2922
- surgical risk and medical optimization in, 2911–2913, 2911*b*–2912*b*
  - anesthesia, 2912
  - prehabilitation, 2912–2913

Germ cell neoplasia in situ, 1692–1693, 1693*b*

Germ cell tumors (GCTs)
- in female pediatric patients, 1120
- retroperitoneal tumors and, 2227–2229

Germ cell/gonadal origins, retroperitoneal tumors and, 2227

Germ cells
- in spermatogenesis, 1396, 1399, 1401
- of testis, 1398, 1398*f*

Gerota fascia, 1667–1668, 1667*f*–1668*f*, 1668*b*, 1865–1866, 1865.e4*f*

GETUG-16 trial, 3663–3664

GFR, Glomerular filtration rate

Giant condyloma acuminatum, of penis, 1742.e1*f*, 1742.e3

Gibson incision, of abdomen, 135–136, 138*f*

Giggle incontinence, 658–660, 2540

Gitelman syndrome, 349

Glans approximation procedure (GAP), 907*f*, 920–921

Glans dehiscence, 937, 938*f*

Glans meatus and penile shaft (GMS) score, 907–908, 908*f*

Glans penis, 1383–1384

Glanular adhesions, of penis, 874–875, 874*f*

Glanular urethra, 305

Gleason grading system, 3507–3508, 3508*f*, 3509*b*, 3510–3511

Gleason scoring system, of localized prostate cancer, 3526

Glenn-Anderson technique, for vesicoureteral reflux in children, 840, 840*f*

Glial-derived neurotrophic factor (Gdnf)/RET, vesicoureteral reflux and, 491.e1

Global Action Plan Prostate Cancer Active Surveillance (GAP3), 3545

Global Evaluative Assessment of Robotic Skills (GEARS), 470

Global Objective Assessment of Laparoscopy (GOALS), 470

Global polyuria, 2667, 2668*t*

Glomerular capillary tuft, 335–336

Glomerular disease, 258–259

- in children, 344–348, 344*b*
  - nephrotic syndrome, 344–345

Glomerular filtration rate (GFR), 341, 1905–1914

- aging and, 2905
- in AKI, 1921, 1922*t*
- clinical assessment of, 1905, 1906*f*
- determinants of, 1905

- developmental changes in, 342
- filtrate transport, 1906–1913
- nephron anatomy, 1906, 1906*f*–1907*f*, 1907*b*
- preoperative evaluation of, 2248
- renal hormone effects, 1913–1914
- urinary tract obstruction and
  - in bilateral ureteral obstruction, 791–792
  - renal blood flow and, 791
  - renal vascular resistance and, 791
  - in unilateral ureteral obstruction, 791

Glomerular hematuria, 16–17, 16*t*, 17*f*

Glomerulonephritis, 345–346
- in CKD, 1929

Glomerulosclerosis, with urinary tract obstruction, 781, 782*f*

Glucocorticoid-induced hypercalcemia, 2020

Glucocorticoids
- in adrenal cortex physiology, 2357, 2358*t*
- hypercalcemia induced by, 2020

Glucose
- homeostasis, 2665–2666
- in urine, 19–20

Glucosuria, 479

Glue, for laparoscopic and robotic surgery, 215.e2

Glutamate, in efferent pathways to bladder, 2488, 2489*f*

Glutaraldehyde cross-linked (GAX) bovine collagen (Contigen), for female urinary incontinence, 2893–2894, 2894*f*

Gluteal compartment syndrome, 262

Glycine, in efferent pathways to bladder, 2488

Glycosaminoglycans
- for BPS/IC treatment, 1244–1245
- in crystal formation, 2014
- in crystal matrix, 2015

layer, of bladder urothelium, 2467–2468

GnRH, Gonadotropin-releasing hormone

GnRH analogues, for priapism, 1553

GOALS, Global Objective Assessment of Laparoscopy

Goldman's cardiac risk index, 120*t*

Gonadal descent, 318–322

Gonadal dysfunction, opioid abuse and, 1426–1427

Gonadal dysgenesis, 1001–1005

- mixed, 998*t*, 1002–1004, 1003*f*, 1003*b*, 1004*t*
- partial, 1004
- 46,XX “pure,”, 998*t*, 1002
- 46,XY complete, 998*t*, 1004–1005, 1005*f*

Gonadal stage of differentiation, 993–994, 994*f*, 994*b*

Gonadal stromal tumors, in male pediatric patients, 1124, 1124*f*

Gonadal veins, 1672–1673

- dissection of, for RPLND, 1716

Gonadoblastomas, 1708

Gonadotropin-releasing hormone (GnRH), 1390, 1391*f*, 1391*t*

Gonadotropin-releasing hormone (GnRH) antagonists, to facilitate bladder filling and urine storage, 2713.e3

Gonads, development of, 317–322, 318*f*, 321*f*–322*f*, 322*b*

Goniometer, 912

Gonocytes, 951, 1399

Goodpasture syndrome, 347

GPS, Genital Perception Score

Grading systems, in perinatal urology, 358–361

Graduated introducer, 170

Grafts
  for pelvic organ prolapse reconstructive surgery, 2776
    anterior compartment, 2783, 2785*f*
    biologics *versus* mesh, 2787
    cadaveric fascia, 2781*t*–2782*t*, 2786, 2786*f*
    polypropylene mesh, 2781*t*–2782*t*, 2783–2786, 2786*f*
    porcine dermis, 2781*t*–2782*t*, 2786–2787, 2787*f*
    posterior compartment, 2829
  for pubovaginal sling, 2834–2835
    harvest for, 2837, 2837*f*
  for renal transplantation, 1058, 1058.e2*f*
  for urethral and penile reconstruction, 1805–1807, 1806*f*
    dermal, 1805–1806
    full-thickness skin, 1805, 1806*f*
    oral mucosa, 1806, 1806*f*
    split-thickness skin, 1805
    vein, 1806
  for urethral stricture disease, 1821*f*–1823*f*
Granuloma inguinale, 1260
Granulomatous disease
  hypercalcemia in, 2020
  hypercalciuria in, 2050
Granulomatous orchitis, 1219
Granulomatous prostatitis, histopathology, 1203
Granulosa cell tumors, of testis, 1708
Grasping instrumentation, for laparoscopic and robotic surgery, 218
Gray-scale ultrasound, 73
Greater omentum, in vesicovaginal fistula repair, 2940
Groin pain, 2880
  in mesh complication, 2881–2882
Gross hematuria, 252–253, 400–401
Gross tumor volume (GTV), 3590
Growth

    - impairment, and chronic kidney disease, 354–355
    - in prune-belly syndrome, 600
    - regulation, in urinary tract obstruction, 783–784
- Growth factors
    - in benign prostatic hyperplasia, 3309–3310, 3310*f*
    - in tubulointerstitial fibrosis, 787–788
- GRS, Gender reassignment surgery
- Grynfeltt lumbar triangle, 169
- GTV, Gross tumor volume
- Guaifenesin, in stone formation, 2033
    - surgical management of, 2077.e2–2077.e3
- Guanine, 1346.e1, 1346.e2*f*
- Guanylyl cyclase pathway, in ED, 1498
- Guarding reflex, in bladder filling, 2515
- Gubernacular anomalies, cryptorchidism and, 962–963
- Gubernaculum
    - anomalies of, cryptorchidism and, 962–963
    - development of, testis descent and, 951–952, 952*f*
- Guidewires, 170
    - for ureteroscopy, 197
- Guillain-Barré syndrome (GBS), lower urinary tract dysfunction with, 2624
- Gunshot wounds
    - penile, 3049–3050
    - renal, 1982
        - nonoperative management of, 1986–1987
    - ureteral, 1995–1996
        - diagnosis of, 1995–1996
- GUPI, Genitourinary problem index
- Gut, 324*f*
- GUTB, Genitourinary tuberculosis

Gynecologic history, pelvic floor disorders and, 2527–2528

Gynecologic laparoscopy, ureteral injuries after, 1993

Gynecomastia, hormonal therapy and, 3681–3682

H

Habit training, 2730.e1*t*, 2731

Hailey-Hailey disease, 1285–1286, 1286*f*

Hald-Bradley classification, of voiding dysfunction, 2523–2524, 2523*b*

HALN, Hand-assisted laparoscopic nephrectomy

Haloperidol, for delirium, 2914

Hammock anastomosis, in urinary diversion, 3189

Hammock hypothesis, of urinary incontinence, 2466, 2518, 2596, 2597*b*

Hand-assist devices, for laparoscopic and robotic surgery, 212, 212*f*

Hand-assisted adrenal surgery, 2419

Hand-assisted laparoscopic nephrectomy (HALN), 2296–2297, 2296*f*

Hand-assisted laparoscopy, for kidney, 2281–2282, 2283*f*

Hand port access, for transperitoneal access, 209

Harmonic Scalpel, 466, 466*f*

Harmonic scanning ultrasound, 74, 75*f*

Hasson technique, 271–272, 464
  for achieving extraperitoneal access and developing extraperitoneal space, 209–210, 210*f*
  for achieving transperitoneal access and establishing pneumoperitoneum, 209, 209*f*
  complications related to, 224

Hautmann pouch, for orthoptic urinary diversion, 3245, 3246*f*

Hawthorne effect, 484–485

Hayflick “limit,” aging and, 2905

HBOT, Hyperbaric oxygen therapy

hCG, Human chorionic gonadotropin

HDCT, High-dose chemotherapy

HDRB, High-dose rate brachytherapy

Headache, orgasmic, 1580–1581

Health, norms of, masculinity and, 1416

Health care, global implications for, 2907–2908

Health issues, in geriatric patients, 2920.e13

Health policy, in ED, 1514, 1515*b*

Health-related quality of life (HRQoL), 108

- benign prostatic hyperplasia and, 3319
- pelvic floor disorders and, 2532*t*–2533*t*

Health services, outcomes research and, 101

Heart, 318*f*

- in prune-belly syndrome, 586

Heart and Estrogen/Progestin Replacement Study (HERS), 2710

Heart disease, nocturia and, 2665

Heart rate variability and sympathetic skin response test, 1527

Heavy particle beams, 3594–3596, 3594*f*, 3595*t*

Hedgehog signaling pathway, in prostate development, 3276

Heineke-Mikulicz principle, of urethromeatoplasty, 918, 921*f*

Heineke-Mikulicz procedure, for lower ureteral injuries, 1999

Heineke-Mikulicz urethroplasty, urethral reconstruction and, 3071

Helium, as insufflant choice, 220

Hemangiomas

- congenital, 888
- renal, 2131–2132
- subcutaneous, 888
- urethral, 1776

        - reconstructive surgery for, 1808

Hemangiopericytomas, in retroperitoneum, 2232, 2233*f*

Hematogenous route of infection, 1131.e1

Hematogenous spread, of UTUC, 2194

Hematologic dyscrasias, priapism and, 1542, 1542*b*

Hematoma

- after midurethral sling, 2874
- postoperative, complication of scrotal surgery, 1855
- urinoma compared with, 1988

Hematopoietic stem cell transplantation, for RCC, 2331, 2331*t*

Hematospermia

- patient history of, 6–7
- prostate biopsy and, 3499

Hematuria, 1936

- after transurethral microwave therapy, 3430
- with benign prostatic hyperplasia, 3336
- in children, 342–343, 343*b*
    - cause of, 342*b*, 343
- classification of, 247
- CT and, 50–51
- evaluation of, 247–259
    - for urothelial cancer, 3078
- in geriatric patients, 2920.e11
- gross, 252–253, 386–387, 386*t*
- hemorrhagic cystitis, 253–255, 253*b*, 255*b*
- management of, 247–259
- microscopic, 247–250, 250*b*
- patient history of, 3
- in pregnant, 283–284
- prostatic origin, 255–257, 256*f*, 257*b*
- in renal injuries, 1982–1983
- timing of, 247
- upper tract imaging in diagnostic evaluation of, 248*t*, 251

- upper urinary tract, 258–259, 258*b*–259*b*
- in ureteral injuries, 1995
- urethral bleeding, 257–258, 258*b*
- urinary biomarkers, 248*t*, 252
- urine cytology for, 248*t*, 252
- UTUC causing, 2189–2190

Hematuria catheter, 154, 154*f*

Hematuria-dysuria syndrome, after augmentation cystoplasty, 698.e1

Hemi-Kock pouch

- for orthoptic urinary diversion, 3243–3244, 3244*f*
- procedure for with valved rectum, 3209–3210

Heminephrectomy, laparoscopic, 2299

Hemodynamics

- changes in, with urinary tract obstruction, 791–792, 793*b*
- during laparoscopic and robotic surgery, approach and patient position effects on, 222

Hemoglobinopathies, 451

Hem-o-Lock clips, 216–217, 217*f*, 217*b*, 467

Hemolysin, 429

Hemolytic uremic syndrome (HUS), 347–348

Hemorrhage

- with holmium laser enucleation of prostate, 3438
- with intestinal anastomoses, 3181
- laparoscopic kidney surgery causing, 2306–2307
- with monopolar transurethral resection of prostate, 3417
- partial nephrectomy causing, 2265–2266
- with percutaneous antegrade endopyelotomy, 1949
- tray, for laparoscopic surgery, 226*b*
- during vena caval thrombectomy, 2278

Hemorrhagic cystitis, 253–255, 253*b*, 255*b*, 526

- management of, 254–255, 254*f*

Hemostasis

  - instrumentation, for laparoscopic and robotic surgery, 214–215, 218
  - for monopolar transurethral resection of prostate, 3410–3415

Henoch-Schönlein purpura (HSP), 346–347, 899

Heparin
  - for vena caval thrombectomy, 2266
  - VTE prophylaxis with for laparoscopic and robotic surgery, 231

Heparin sulfate, in crystal formation, 2014

Hepatic cysts, 752

Hepatic dysfunction, during vena caval thrombectomy, 2278

Hepatic function, aging and, 2906

Hepatic resections, RPLND with, 1719–1720

Hepatitis, allografts and, 2835

Hepatitis B, STDs and, 1268–1269, 1269*t*

Hepatitis C, STDs and, 1270

Hepatobiliary evaluation, 121

Hepatorenal ligament, 1865

Hereditary hypophosphatemic rickets with hypercalciuria (HHRH), 2019

Hereditary leiomyomatosis and RCC (HLRCC) syndrome, 1358, 2142*t*, 2144
  - systemic therapy for, 2343

Hereditary nonpolyposis colorectal cancer, genomic alterations in, 1354*t*

Hereditary papillary RCC (HPRCC) syndrome
  - genomic alterations in, 1354*t*, 1358, 2142*t*, 2143–2144
  - systemic therapy for, 2343–2344, 2344*f*

Hereditary pheochromocytoma, 2373, 2374*t*, 2375, 2380

Hereditary prostate cancer (HPC), genomic alterations in, 1354–1355, 1354*t*, 1355*f*

Hereditary renal malignancy, in partial nephrectomy, 2262–2263

Hereditary spastic paraplegia (HSP), lower urinary tract dysfunction and, 2624–2625

Herlyn-Werner-Wunderlich syndrome, 985–986, 986*f*

Hernia, 392, 888–893, 892*b*

- after laparoscopic and robotic surgery, 231
- definitions for, 889, 889*f*
- diagnosis of, 889–890
- embryology of, 888–889
- epidemiology and pathogenesis of, 889
- genetics of, 889
- with intestinal anastomoses, 3180*t*
- as laparoscopic and robotic surgery contraindication, 204
- physical examination of, 890, 890*f*
- radiologic imaging of, 890, 890*f*

Herpes, genital ulcers, 1255*t*

Herpesvirus infection, lower urinary tract dysfunction with, 2621–2622

HERS, Heart and Estrogen/Progestin Replacement Study

HGPIN, High-grade prostatic intraepithelial neoplasia

HHRH, Hereditary hypophosphatemic rickets with hypercalciuria

Hidden incision endoscopic surgery (HIdES), 458, 459*f*

HIdES, Hidden incision endoscopic surgery

Hidradenitis suppurativa (HS), 1291–1292, 1292*f*

HIFU, High-intensity focused ultrasound ablation

High-dose chemotherapy (HDCT), for NSGCTs, 1697–1698

High-dose rate brachytherapy (HDRB), 1767, 3668

- for prostate cancer, 3598–3599
  - as boost with external beam radiation therapy, 3599
  - monotherapy, 3599

High-dose-rate monotherapy, 3599

High-energy linear accelerators, 3587

High-grade prostatic intraepithelial neoplasia (HGPIN), 3506, 3507*f*

High-intensity focused ultrasonography, 3628, 3629*t*–3630*t*, 3631*f*–3632*f* for locally advanced prostate cancer, 3655

High-intensity focused ultrasound ablation (HIFU), for renal tumor ablation, 2319–2321

High-pressure bladder, spinal cord injury with, host defense mechanisms in UTIs and, 1140

Hillier, Thomas, 160

Hindgut, 318*f*

Hinge region, of urothelium of bladder, 2462, 2463*f*

Hippocratic oath, 115, 116*b*

Histamine

in BPS/IC etiology, 1232.e4, 1232.e5*b*

urethral function effects of, 1901–1902

Histamine antagonists, urethral function effects of, 1901–1902

Histamine H_2 receptor antagonists, and ED, 1509

Histology, adrenal, 2351–2352, 2351*f*, 2355*f*, 2356

Histone post-translational modifications, in prostate cancer, 3470

History, Patient history

History of present illness, 1–7

HIV, Human immunodeficiency virus

H-line measurement, 2441–2442, 2442*f*

HO, Hyperbaric oxygen

Hodson-type kidney, 162, 163*f*, 164

HoLEP, Holmium laser enucleation of prostate

Holmium laser

for bladder mesh perforation, 2868–2869

use of, 168–169

Holmium laser enucleation of prostate (HoLEP), 3436

in anticoagulated patient, 3438

- complications with, 3438
  - intraoperative, 3438
  - perioperative, 3438
  - postoperative, 3438
- conclusion for, 3438
- introduction and concept for, 3436
- open prostatectomy *versus*, 3437
- outcomes with, 3437–3438
  - comparative series, 3437–3438
  - single-cohort series, 3437
- technique for, 3436
  - intraoperative, 3436
  - postoperative, 3436
  - preoperative, 3436
- thulium laser *versus*, 3442–3443
- transurethral resection of prostate *versus*, 3437

Holmium:YAG (Ho:YAG) laser, 240, 245*b*

- basic physics of, 244

Homeobox gene, 317

Homogeneous nucleation, 2011

HOPE, Hypospadias Objective Penile Evaluation

Hormonal evaluation, and ED, 1527–1529

Hormonal therapy

- for benign prostatic hyperplasia, 3371

IIEF, International Index of Erectile Function

IIQ, Incontinence Impact Questionnaire

Ileal conduit, 3193–3196, 3194*f*–3195*f*, 3195*t*

- in minimally invasive urinary diversion, 3261–3262

Ileal neobladder, for orthoptic urinary diversion, 3245, 3246*f*

Ileal reservoirs

- continent, 3213–3215, 3214*f*
- for orthoptic urinary diversion, 3243

Ileal ureteral replacement, 2208, 2209*f*

Ileal ureteral substitution

- minimally invasive, for ureteral stricture disease, 1973–1975
- for ureteral stricture disease, 1973–1975, 1974*f*

Ileal vesicostomy, 3197–3198

Ileocecal conduit, colon conduit and, 3196, 3198*t*

Ileocecal valve

- for continent urinary diversions, 709–710
- in ileocecocystoplasty, 694
- imbricating, in robot-assisted intracorporeal continent cutaneous diversion, 3269

Ileocecocystoplasty, 694, 694*f*–695*f*

Ileocolic anastomosis, in robot-assisted intracorporeal continent cutaneous diversion, 3269, 3269*f*

Ileocystoplasty, 692–693, 693*f*

Ileostomy bowel diversions, ammonium acid urate stones from, 2032

Ileovesicostomy, 702, 702*b*

Ileum

- selection, 3162
- tapering of, in robot-assisted intracorporeal continent cutaneous diversion, 3269

Ileus, after RPLND, 1731

Iliac aneurysm, as laparoscopic and robotic surgery contraindication, 204

Iliac arteries, 2451–2452, 2451*t*

Iliac crests, 2428*f*

Iliac lymph nodes, 2433

Iliac spines, 2428*f*, 2445*f*

Iliac veins, 2452

Iliacus, 1658, 1662*f*–1665*f*, 1664*t*

Iliococcygeus muscle, 2430–2432, 2432*f*

Iliococcygeus suspension, for apical pelvic organ prolapse repair, 2797–2798, 2799*f*

Iliohypogastric nerve, 2447*f*–2448*f*, 2453, 2453*t*

Ilioinguinal nerve, 2447*f*–2448*f*, 2453, 2453*t*

Illicit drug use, patient history of, 9

ILND, Inguinal lymphadenectomy

IMA, Inferior mesenteric artery

Image guidance, to prostate cancer, 3589

Image-guided radiation therapy, for prostate cancer, 3589–3590, 3591*f*–3592*f*

Image storage, ultrasonography, 76, 77*f*

Imaging
  - in adrenal mass evaluation, 2394–2398, 2396*f*–2397*f*, 2397*b*
  - for benign prostatic hyperplasia, 3347
  - for male urinary incontinence, 2543
  - for pediatric urology, 388–391
    - prenatal ultrasonography, 389
    - renal bladder ultrasound, 388–389
    - ultrasonography, 388–389
  - of pheochromocytoma, 2375, 2376*f*
  - techniques, for UTIs, 1143–1144, 1144*b*

    - indications, 1144*b*
    - radionuclide studies, 1144.e1
    - ultrasonography, 1144
    - voiding cystourethrogram, 1144

Imidafenacin, to facilitate bladder filling and urine storage, 2682, 2682*t*

Imipramine (Tofranil)

- to facilitate bladder filling and urine storage, 2682*t*, 2702
- for nocturnal polyuria, 2668, 2673*t*
- for stress urinary incontinence in women, 2714–2715
- ureteral response to, 1888

Imiquimod cream, for condylomata acuminata, 1742.e3

Immune checkpoint blockade, 1342, 1342*f*

- in bladder cancer, 1342
- in kidney cancer, 1343
- in prostate cancer, 1343

Immune editing hypothesis, 1336, 1337*f*

Immune response, pathogen recognition, 1138–1139

ImmunoCyt, of bladder tumor, 3081

Immunoglobulin A (IgA) nephropathy, 346

Immunoglobulins, in prostatic secretions, 3298*t*, 3302

Immunologic effects, of laparoscopic and robotic surgery, 223

Immunologic function, aging and, 2906

Immunology, immune response in GU cancers, 1333–1345, 1336*b*

- adaptive immune system, 1334–1336, 1335*f*
- immune editing hypothesis, 1336, 1337*f*
- inflammation effects in, 1336, 1337*f*–1338*f*, 1338*b*
- innate immune system, 1333–1334, 1334*f*–1335*f*, 1334*t*–1335*t*

Immunomodulator drugs, for BPS/IC oral therapy, 1241*t*, 1242–1243

Immunosuppressed patients, penile implants for, 1596

Immunosuppression, in end stage renal disease, 357

Immunotherapy

- for castration-resistant prostate cancer, 3697–3699, 3699*b*
- for GU cancers, 1333–1345, 1341*b*, 1343*b*
  - BCG in bladder cancer, 1333, 1334*f*, 1338–1339, 1339*f*

        - cancer vaccines, 1339–1340, 1340*f*–1341*f*
        - combination, 1343–1345, 1345*f*
        - immune checkpoint blockade, 1342, 1342*f*
    - for non-muscle-invasive bladder cancer, 3099–3103, 3103*b*
        - Bacille Calmette-Guérin, 3099–3100
        - interferon, 3102–3103
        - investigational, 3103
    - for UTUC, 2223–2224
- IMPACT study, 3697, 3697*f*
- Impedance, in ultrasonography, 71, 71*f*
- Imperforate hymen, 395, 396*f*, 978–979, 979*f*
- Implants, for ED, 1582
    - inflatable, 1582, 1583*f*
    - semirigid rods, 1582, 1583*f*, 1584*t*
- IMT, Inflammatory myofibroblastic tumor
- IMV, Inferior mesenteric vein
- In vitro fertilization, 1428, 1445.e3
- Incidental urolithiasis, 402
- Incidentalomas, adrenal
    - adrenal surgery for, 2409*b*
    - evaluation of, 2394, 2394*t*
- Incision instrumentation, for laparoscopic and robotic surgery, 214–215
- Incisional hernia, after laparoscopic and robotic surgery, 231
- Inclusion cysts, 882–883, 882*f*
- Inconspicuous penis, 394, 872*t*, 877–879, 879*f*
- Incontinence Impact Questionnaire (IIQ), 110, 111*t*
- Incontinence Quality of Life Instrument (I-QOL), 111*t*
- Incontinence Symptom Index (ISI-P), 477
- Incontinent urinary diversion, for neuromuscular dysfunction of lower urinary tract, 636–637

Increased through transmission, in ultrasonography, 72, 72*f*

Index lesion hypothesis, multifocality of prostate cancer *versus*, 3617–3620, 3619*t*, 3620*f*

Index of Premature Ejaculation (IPE), 112*t*

Indiana pouch, 3220–3224, 3222*f*–3223*f*

Indigo carmine, toxicity of, 1994

Indinavir sulfate (Crixivan), in stone formation, 2032–2033

Indirect inguinal hernia, 889

Indirect medical risk factors, in bladder tumor, 3077

Indium-111 (^{111}In), 91, 92*t*

- capromab pendetide scanning, for biochemical recurrence after radical prostatectomy, 3661

Indomethacin

- to facilitate bladder filling and urine storage, 2682*t*, 2703
- urethral function effects of, 1902

Induction process, 785–786, 786*f*

Indwelling catheters, for urinary incontinence, in geriatric patients, 2920.e5

Indwelling orthopedic hardware, antimicrobial prophylaxis for uncomplicated urologic procedures and, 1201

Infected hydronephrosis and pyonephrosis, 1174, 1174*f*

Infection

- after midurethral sling, 2870–2871
- after prostate biopsy, 3499
- with artificial urinary sphincter, 3005–3006
- in BPS/IC etiology, 1232.e1–1232.e2
- complicated, 1129, 1130*b*
- complication of scrotal surgery, 1856
- from cutaneous diseases of external genitalia
    - balanitis, 1288
    - balanoposthitis, 1288, 1289*f*
    - candidal intertrigo, 1293–1294, 1294*f*
    - cellulitis, 1288–1289, 1290*f*

        - corynebacterial infection (trichomycosis axillaris and erythrasma), 1292–1293, 1293*f*
        - dermatophyte infection, 1294–1295, 1295*f*
        - ecthyma gangrenosum, 1293, 1294*f*
        - erysipelas, 1288–1289
        - folliculitis, 1290–1291, 1291*f*
        - Fournier gangrene, 1289–1290, 1290*f*
        - furunculosis, 1291, 1291*f*
        - genital bite wounds, 1293, 1294*f*
        - hidradenitis suppurativa, 1291–1292, 1292*f*
        - infestation, 1295–1296, 1296*f*
        - STDs, 1288, 1289*f*
    - host factors increasing risk of, 1193*b*
    - and inflammation, and male infertility, 1432
    - with intestinal anastomoses, 3180
    - penile implant and, 1591–1593, 1592*f*, 1593*b*
    - with percutaneous antegrade endopyelotomy, 1949
    - preoperative care for pediatric patients with, 447–448
    - prostate cancer and, 3461, 3462*f*
    - prostatitis and, 1207
    - renal transplantation and, 1056–1057, 1061
    - ureteral anomalies and, 801–802
    - ureteral function effects of, 1899
    - with urinary intestinal diversion, 3198–3205, 3205*b*
    - UTUC risk and, 2187

Infection calculi, 2063–2065, 2063*f*, 2064*t*, 2065*b*

Infection stones, 2030–2031
    - bacteriology of, 2030–2031, 2031*t*
    - epidemiology of, 2031
    - pathogenesis of, 2030, 2030*f*

Infectious granulomatous nephritis
    - malacoplakia, 1179–1181, 1180*f*
    - renal echinococcosis, 1181.e1, 1181.e2*f*
    - XGP, 1177–1179, 1178*f*–1179*f*

Infective disorders, and delayed ejaculation, 1575

Inferior epigastric artery, 136*f*

Inferior mesenteric artery (IMA), in radical nephrectomy, 2261

Inferior mesenteric vein (IMV), in radical nephrectomy, 2261

Inferior vena cava (IVC)

- filtration and permanent interruption of, 2277
- patching, replacing, and interrupting of, 2276–2277, 2277*f*
- in radical nephrectomy, 2258, 2258*f*, 2258.e1*f*
- RCC involvement of, 2174–2176, 2175*f*–2176*f*, 2298
- resection of, RPLND with, 1718–1719
- in retroperitoneum, 1672

Inferior vesical artery, 1380, 1380*f*

Infertility

- ligation with resulting, complication of scrotal surgery, 1856
- male, 1428–1452
    - abdominal, imaging of, 1444, 1445*f*
    - assisted reproduction, 1445–1452, 1445.e3, 1445.e3*t*
    - causes of, 1446–1447
    - and childhood diseases, 1432–1434
    - and chromosomal numerical disorders, 1445–1446
    - cranial, imaging of, 1444–1445, 1445*f*
    - developmental disorders and, 1449–1450
    - diagnoses and therapies for, 1445, 1452*b*
    - and ejaculatory dysfunction, 1450–1451
    - epidemiology of, 1428
    - epigenetic anomalies and, 1446
    - and extratesticular endocrine dysfunction, 1448–1449
    - and genetic syndromes, 1445–1446
    - and genetics, 1433
    - and genomic assessment, 1442–1443
    - history of, 1428–1434, 1429*t*, 1434*b*
    - and hypogonadotropic hypogonadism, 1447–1448
    - imaging of, 1443–1445, 1445*b*
    - and infections and inflammation, 1432
    - laboratory evaluation of, 1436–1443, 1443*b*
    - and microductal obstruction, 1447, 1447*f*
    - and pediatric surgery, 1432
    - physical examination of, 1434–1436, 1436*b*
    - and pituitary dysfunction, 1447–1448
    - and spermatogenic dysfunction, 1446
    - and steroidogenic dysfunction, 1447
    - structural chromosomal anomalies and, 1446

- and structural sperm abnormalities, 1451–1452
- testicular dysgenesis hypothesis, and childhood diseases, 1433
- testis histopathology and, 1445, 1445.e1*f*–1445.e2*f*, 1445.e2*b*
- vasography for, 1444
- venography for, 1444

TGCT and, 1690

Infestation, as cutaneous disease of external genitalia, 1295–1296, 1296*f*–1297*f*

Infibulation, 987–988, 988*f*

Inflammation
- in BPS/IC etiology, 1232.e2–1232.e3, 1232.e3*b*
- in cancer immune response, 1336, 1338*b*
- pathways of, in benign prostatic hyperplasia, 3311, 3312*f*
- prostate cancer and, 3461, 3462*f*
- prostatitis and, 1207
- triggers for, 3477*b*

Inflammatory bowel disease, ammonium acid urate stones from, 2032

Inflammatory cell infiltration, in tubulointerstitial fibrosis, 787

Inflammatory myofibroblastic tumor (IMT), in pediatric patients, 1119

Inflammatory strictures, 1815

Informed consent, 115–118
- elements of, 117–118
- for erectile dysfunction, surgery for, 1582–1583, 1584*b*
- exception to, requirement, 118
  - emergency situations, 118
  - patients without decision-making capacity, 118
  - pediatric patients, 118
- history of, 116–117
- quality of, 118

Infraumbilical, 135

Infundibulopelvic stenosis, 739–740, 740*f*

Inguinal canal, anatomy of, 2445–2447, 2448*f*

Inguinal hernia
- epidemiology and pathogenesis of, 889

- female, 988
- surgical repair of, 890–891
    - complications with, 891
    - laparoscopic, 891–892
    - scrotal approach to, 891
    - standard, 891

Inguinal incisions, in urologic surgery, 140–141
- inguinal ligament, incision above, 140–141, 141*f*
- and pelvic lymphadenectomy, in penile cancer, 141, 141*f*

Inguinal ligament, incision above, 140–141, 141*f*

Inguinal lymph nodes, 1386
- anatomy of, 1790, 1791*f*

Inguinal lymphadenectomy (ILND), 1753–1756
- in clinically negative groins
    - DSNB, 1760–1761
    - laparoscopic and robotic ILND, 1761
    - modified complete ILND, 1761
    - sentinel lymph node biopsy, 1760
    - superficial inguinal node dissection, 1761
- complications of, 1801–1802
- indications for
    - expectant management of, 1759–1760, 1760*t*
    - modified procedures, 1760–1762
    - traditional procedures, 1761–1762
    - watchful waiting, 1759
- palpable adenopathy in selection for, 1753–1756
- for penile cancer
    - immediate *versus* delayed, 1756
    - indications for modified procedures, 1760–1762
    - indications for traditional procedures, 1761–1762
    - indications for watchful waiting, 1759
    - molecular prognostic markers for, 1759, 1759*t*
    - morbidity *versus* benefit, 1756–1757, 1756*t*, 1757*f*
    - palpable adenopathy in selection for, 1753–1756
    - prognostic significance of metastatic disease, 1753, 1754*t*–1755*t*
    - tumor histology in selection for, 1757–1759, 1758*t*
- postoperative care after, 1801
    - antibiotics for, 1801
    - anticoagulation for, 1801

    - bed rest in, 1801
    - compressive dressings and stockings for, 1801
    - dietary considerations of, 1801
    - drainage, 1801
  - prognostic significance of metastatic disease, 1753, 1754*t*–1755*t*
- Inguinal node dissection, 1790–1803, 1803*b*
  - anatomic considerations for
    - inguinal anatomy, 1790–1791, 1791*f*
    - penile lymphatics, 1790
    - urethral lymphatics, 1790
  - endoscopic anatomy of, 1791
  - follow-up after, 1802–1803, 1802*t*
  - imaging evaluation of, 1791–1792
  - oncologic control after, 1802, 1802*t*
  - patient before surgery, preparation of, 1800–1801
    - antibiotics, 1800–1801
    - anticoagulation, 1801
    - bowel cleansing, 1801
  - for penile cancer, 1792, 1792*b*
    - nonpalpable inguinal adenopathy, 1792–1796
    - palpable inguinal adenopathy or positive inguinal lymph nodes, 1796–1800
    - surgical management of, 1792
- Inguinal nodes
  - palpable adenopathy in selection for, 1753–1756
  - penile cancer metastasis to
    - imaging studies for, 1747–1748
    - risk-based management for, 1762–1765, 1763*f*–1764*f*
  - treatment of, for penile cancer, 1753–1765, 1762*b*
    - palpable adenopathy in selection for, 1753–1756
    - prognostic significance of metastatic disease, 1753, 1754*t*–1755*t*
- Inguinal orchiopexy, 966–967
- Inherited genetic markers, as prostate cancer biomarkers, 3488–3489
- Inhibin, 1390, 1391*f*
- Inhibitors, of crystal formation, 2014–2015
- Injection therapy
  - for bladder neck reconstruction, 687

- for female stress urinary, in geriatric patients, 2920.e5
- for prostate, 3446–3447

Injuries, of bladder, 3054–3057, 3055*b*–3056*b*

INK4A gene (p16), in bladder cancer, 1350

Innate immune system, 1333–1334, 1334*f*–1335*f*, 1334*t*

- cytokines and chemokines, 1333–1334, 1335*f*, 1335*t*

Innervation

- of bladder, 2456
- of labium majus, 2436
- motor nerve, of bladder smooth muscle, 2465, 2465*f*, 2480, 2480*f*
- of pelvis
  - female, 2433–2434
  - male, 2447*f*–2448*f*, 2453, 2453*f*, 2453*t*, 2454*b*
- of vagina, 2438

Innominate bones, 2444

Inositol 1,4,5-trisphosphate (IP3), in ureteral contractions, 1885

In-oxine, 96

Insemination, intrauterine, 1445.e3

Insensible urinary incontinence (IUI), 2540, 2581

- overactive bladder and, 2637
- pathophysiology of, 2597

INSS, International Neuroblastoma Staging System

Instillation therapy, 2220, 2221*f*

Institutional support, in transitional urology, 1045

Instrument development, 108

Instrumental activities of daily living (IADLs), of geriatric urology patient, 2909

Instrumentation, for visualization, 213, 213.e1*f*

Insufflant, for laparoscopic and robotic surgery, 220

Insufflation, for laparoscopic and robotic surgery, complications related to, 224–225

Insulin resistance, low urine pH and, 2027–2028

Insulin-like growth factor-3, 1392

Insulin-like growth factors (IGFs)

- in compensatory renal growth, 794–795
- in prostate cancer, 3463

Integral theory, 2596, 2597*b*, 2831

Integrated endoscopy systems, for laparoscopic surgery, 205–206, 205.e1*f*

Intensity-modulated radiation therapy, for prostate cancer, 3588–3589, 3589*f*, 3589*t*

Interaortocaval lymph nodes, 1372

Inter-α-trypsin, in crystal formation, 2015

Intercellular communication, penile erection and, 1500

Interference, of ultrasound waves, 71, 71*f*

Interferon alfa-2b (IFNs), for PD, 1612–1613, 1617*t*

Interferon-gamma release assays (IGRAs), for genitourinary tuberculosis, 1311

Interferons (IFNs)

- for clear cell RCC, 2329, 2329*t*
- for condylomata acuminata, 1742.e3
- for metastatic RCC, 2326, 2326*f*, 2327*t*
- for non-muscle-invasive bladder cancer, 3102–3103
- for RCC, 2178–2179

Interlabial masses, 395, 398*b*

Interleukin-2 (IL-2), for metastatic RCC, 2326, 2329–2331, 2330*t*

Interleukin-18 (IL-18), in tubulointerstitial fibrosis, 788

Interleukins, 1334, 1335*f*, 1335*t*

Interlobar arteries, 1869

Interlobular arteries, of kidney, 1869, 1870.e1*f*

Interlobular veins, of kidney, 1869–1870

Intermediate cells, of prostate, 3278*f*, 3279

Intermediate junctions, ureteral, 1877, 1883

Intermediate stratum, 2427, 2429*f*

Intermittent testicular torsion, 1855

Internal genitalia, male, development of, 1392, 1392*f*

Internal iliac arteries, 1873.e1*f*, 1874

Internal iliac lymph nodes, 1381

Internal iliac veins, 1381, 1874

Internal pudendal artery, 1381, 1807.e4*f*

Internal spermatic artery, 1393, 1394*f*

Internal sphincter
  male sphincteric mechanisms and, 2594
  urodynamic studies of, 2569

Internal urethrotomy, for urethral stricture disease, 1818

International Association for the Study of Pain, 448

International Classification of Vesicoureteral Reflux, 498*t*

International Consultation on Incontinence (ICI)
  Oxford guidelines
    for behavior therapy, 2722.e4*b*
    to facilitate bladder filling and urine storage, 2681*t*
  pelvic floor disorder questionnaires, 2531, 2532*t*–2533*t*

International Consultation on Incontinence Modular Questionnaire-male LUTS (ICIQ-MLUTS), 3344

International Consultation on Incontinence Questionnaire (ICIQ), 111*t*

International Consultation on Incontinence Questionnaire Bladder Diary (ICIQ-BD), 2541, 2541*f*

International Consultation on Incontinence Questionnaire Female Lower Urinary Symptoms (ICIQ-FLUTS), 111*t*

International Consultation on Incontinence Questionnaire Male Lower Urinary

Tract Symptoms (ICIQ-MLUTS), 2541, 2541.e1*f*–2541.e2*f*

International Consultation on Incontinence Questionnaire Urinary Incontinence Short Form (ICIQ-UI-SF), 2541, 2542*f*

International Continence Society (ICS)

- classification of voiding dysfunction, 2517, 2521*b*
- nocturia definition of, 2664
- transient incontinence causes, 2525, 2526*t*

International Germ Cell Cancer Collaborative Group (IGCCCG), risk classification for advanced GCTs, 1690, 1691*t*

International Index of Erectile Function (IIEF), 112*t*

International Neuroblastoma Staging System (INSS), 1090*t*–1091*t*, 1091

International Prostate Symptom Score (IPSS), 4*t*–5*t*, 109, 110*t*

- for benign prostatic hyperplasia, 3344
- for male urinary incontinence, 2541
- for nocturia, 2664
- for pelvic floor disorders, 2531

International Reflux Study in Children, 515

International Society for Sexual Medicine, and Premature ejaculation, 1565–1567

- rationales for, 1567.e1–1567.e2

International Society of Urological Pathology, Gleason grading system, 3511

Interpolar calyx, 166

Interposition material, in urethrovaginal fistulae, 2951

Interrupted-shaped curve, 480

Interstitial cells

- bladder outlet obstruction and, 2506
- of detrusor muscle, 2477–2478, 2478*f*

Interstitial cystitis, female sexual dysfunction and, 1657

Interstitium, of testis, 1394–1396

- in testosterone synthesis, 1394

Interventional angiography, for priapism, 1560–1561, 1561*f*

Intestinal anastomoses, in urinary intestinal diversion, 3169–3184, 3184*b*
- abdominal stomas with, 3182–3183
  - complications of, 3183–3184, 3186*t*
  - flush, 3182–3183
  - loop end ileostomy, 3183, 3183*f*
  - nipple (rosebud), 3182, 3182*f*–3183*f*
- with biofragmentable ring, 3179
- complications of, 3179–3181
  - bowel obstruction, 3180–3181, 3180*t*, 3181*f*
  - fistulas, 3179–3180
  - hemorrhage, 3181
  - infection, 3180
  - intestinal stenosis, 3181, 3181*f*
  - pseudo-obstruction, 3181
  - sepsis, 3180
- complications of isolated intestinal segment, 3181–3182
  - intestinal stricture, 3181
  - segment elongation, 3181–3182, 3182*f*
- compression, 3179
- laparoscopic and robotic, 3178–3179, 3178*f*–3179*f*
- stapled, 3176–3178
  - ileal-ileal, 3177–3178, 3178*f*
  - ileocolonic end-to-end, 3176, 3176*f*
  - ileocolonic with circular device, 3177, 3177*f*
- types of, 3174–3176
  - end-to-side ileocolic, 3175–3176, 3176*f*
  - ileocolonic end-to-end, 3176, 3176*f*
  - single-layer suture, 3175, 3175*f*
  - two-layer suture, 3174–3175, 3175*f*

Intestinal antireflux valves, in urinary intestinal diversion, 3189–3191
- intussuscepted ileal valve, 3190–3191, 3191*f*
- intussuscepted ileocecal valve, 3189–3190, 3191*f*
- nipple valve, 3191, 3192*f*

Intestinal motility
  pneumoperitoneum effects on, 222
  urinary intestinal diversion and, 3203
Intestinal neobladders, pharmacologic therapy in, to facilitate bladder filling and urine storage, 2712–2713
Intestinal segments
  for antireflux procedure, 683–685
  in augmentation cystoplasty, 692
    effects of, 696–697
  neuromechanical aspects of, 3204–3205
  used in urinary diversion, minimally invasive, 3268
Intestinal stenosis, with intestinal anastomoses, 3181, 3181*f*
Intestinal stricture, with intestinal anastomoses, 3181
Intestinal tract abnormalities, with cloacal exstrophy, 575
Intimal fibroplasia, 1916, 1916*f*
Intra-abdominal pressure, for laparoscopic and robotic surgery, 220–221
Intra-abdominal vessels, injury of, during laparoscopic and robotic surgery, 226
Intracavernosal injection, in ED, 1534–1535, 1535*t*
Intracorporeal lithotripsy, 2109–2113
  ballistic lithotripsy, 2111–2112, 2112*f*
  combination ballistic and ultrasonic devices in, 2112–2113
  commonly used, 242*t*
  electrohydraulic lithotripsy, 2109–2110, 2110*f*
  laser lithotripsy, 2110–2111
  pneumatic, 243*b*
    basic physics of, 243
    for percutaneous nephrolithotomy, 243.e1
    tissue effects of, 243
    ureteroscopy with, 243.e1
  ultrasonic lithotripsy, 2112, 2112*f*
Intracorporeal neobladder, in minimally invasive urinary diversion, 3262–3273, 3263*t*

Intracranial aneurysms (ICAs), 752

Intradetrusor therapies, for BPS/IC treatment, 1245–1246

Intraductal carcinoma of the prostate (IDC-P), 3506

Intralabial masses, in female, 386

Intraluminal lithotripsy, ureteroscopic

- devices for, 197
- retropulsion prevention devices for, 198, 198*f*
- stone retrieval devices, 198
- ureteral access sheaths for, 199, 199*f*, 199*t*

Intramural ureter, tumor confined to, 2211–2212, 2213*f*, 2215*f*

Intraoperative consultation, 296–304, 298*b*

- bladder injury, 299–300, 303*b*
- decision making, 296–297, 297*f*
- documentation, 297–298
- ethical considerations, 296
  - patient-physician relationship, 296
- placental cases, 303–304
- renal injury, 302–303
- ureteral injury, 300–302
- urethral injury, 298–299

Intraoperative floppy iris syndrome (IFIS), α1-adrenergic blockers and, 3370

Intraoperative management, in urologic surgery, 125–134

- anesthetic considerations, 130–132
- antibiotic prophylaxis, 127–128, 127*b*
- pain management, 134
- patient management, 125
- patient positioning, 126–127, 126*b*, 128*b*
- patient safety, 126
- skin preparation, 132–133
- transfusion considerations, 133
- venous thromboembolic prophylaxis, 128–130, 129*t*–131*t*, 131*b*

Intraoperative obturator nerve injury, 262

Intraoperative planning, 3596

Intraoperative urethral injury, 2883

Intraoperative vascular complications, 269–270

Intraperitoneal urine leak, in robotic prostatectomy, 3580

Intraprostatically injected drugs, to facilitate bladder filling and urine storage, 2713.e2–2713.e3

Intrarenal schwannoma, 2132

Intrarenal vasculature, 162–164, 163*f*

Intrascrotal pain, surgical management of, 1853–1855

Intratesticular varicocele, 901–902

Intratubular germ cell neoplasia (ITGCN), 1680

Intraurethral valve-pump, for women with impaired detrusor contractility, 2902–2903

Intrauterine insemination, 1445.e3, 1445.e3*t*

Intravaginal devices, for urinary incontinence, 2736–2737, 2736.e1*f*, 2737*f*, 2737.e1*f*

Intravaginal slingplasty, 2831, 2851

Intravascular volume management, for pheochromocytoma, 2379*f*, 2380

Intravenous general anesthesia, 132

Intravenous pyelography, 415, 806, 807*f*

- of ureteral injuries, 1995–1996, 1996*f*

Intravenous urography (IVU), 35, 36*f*

- for genitourinary tuberculosis diagnosis, 1312, 1312*f*–1313*f*
- for ureterovaginal fistula, 2929, 2944*f*
- for vesicovaginal fistula, 2929

Intravesical approach, for bladder diverticula, 3013–3015, 3013*f*–3014*f*

Intravesical chemotherapy, for non-muscle invasive bladder cancer, 3103–3105, 3104*t*, 3105*b*

- combination therapy, 3105

- doxorubicin, 3103–3104
- mitomycin C, 3104–3105
- novel agents, 3103
- to prevent implantation, 3103–3105
- thiotepa, 3103
- valrubicin, 3104

Intravesical electrotherapy (IVE), for detrusor underactivity, 2661–2662

Intravesical pressure, increasing
- external compression for, 2902–2903
  - to facilitate bladder emptying, 2716–2718
- to facilitate bladder emptying, 2902–2903
- intraurethral valve-pump for women with impaired detrusor contractility, 2902–2903
- reflex contraction promotion or initiation, 2902
- stimulated myoplasty, 2903

Intravesical prostatic protrusion (IPP), 3348

Intravesical stimulation, 2747–2748

Intravesical therapies, for BPS/IC treatment, 1241*t*, 1244–1247, 1245*b*
- Clorpactin, 1244.e1
- DMSO, 1244
- glycosaminoglycans, 1244–1245
- intradetrusor therapies, 1245–1246
- silver nitrate, 1244.e1

Intrinsic apoptotic pathway, 1366.e1, 1366.e1*f*

Intrinsic kidney injury, 1923

Intrinsic renal disease, AKI due to, 1923

Intrinsic sphincter dysfunction, 2518

Intrinsic sphincteric deficiency (ISD), 2518
- causes of, 2595–2596
- midurethral sling for, outcomes of, 2859–2860
- quantification of, 2562
- sling procedure and, 2834
- stress urinary incontinence and, 2597, 2757

  - urinary incontinence and, 2595–2596

Introitus, 1627.e1

Intubated ureterotomy, for ureteropelvic junction obstruction, 1961–1962, 1963*f*

Intussuscepted ileal valve, 3190–3191, 3191*f*

Intussuscepted ileocecal valve, 3189–3190, 3191*f*

Inverse treatment planning, 3588

Inverted papilloma, of bladder, 3081

Involuntary detrusor contractions (IDCs), 2560

Iodinated intravenous contrast agents, 292

Iodine-123 (^{123}I), 91

Iodine-124 (^{124}I), 91

Ion channels
  - in detrusor muscle, 2474, 2474*f*
  - in ED, 1499

Ionic transport, across bladder urothelium, 2469

Ionizing radiation, technique of, 403, 403*b*

IPE, Index of Premature Ejaculation

Ipilimumab, 2146
  - for RCC, 2332

IPP, Intravesical prostatic protrusion

Ipsilateral vesicoureteral reflux, bladder diverticula with, 2971

IPSS, International Prostate Symptom Score

I-QOL, Incontinence Quality of Life Instrument

IRE, Irreversible electroporation

Irinotecan, for penile cancer, 1770

Irreversible electroporation (IRE), 3628–3632, 3635*f*, 3636*t*
  - for renal tumors, 2322

Irritable bowel syndrome (IBS), cross-organ sensitization in, 2486

Irritative lower urinary tract symptoms, patient history of, 3

Isaacs syndrome, lower urinary tract dysfunction and, 2630

Ischemic nephropathy, 1915, 1921–1935

Ischemic priapism, 1539, 1540*f*

  epidemiology and pathophysiology of, 1541–1545, 1543*f*

  penile implants in, 1596

Ischial spine, 2427, 2428*f*

Ischiococcygeus muscle, 2432*f*, 2434

Ischiorectal fossa, 2435

ISD, Intrinsic sphincteric deficiency

ISI-P, Incontinence Symptom Index

Island flaps, for urethral and penile reconstruction, 1807

Island onlay flap procedure (OIF), 924–925, 926*f*

Isoproterenol, ureteral response to, 1885, 1888

Isovolumetric pressure, 2659

ITGCN, Intratubular germ cell neoplasia

IUI, Insensible urinary incontinence

IV pyelography (IVP)

  of renal injuries, 1985, 1995–1996, 1996*f*

  for renal tumor evaluation, 2134

IVC, Inferior vena cava

IVC filters, for vena caval thrombectomy, 2266–2267

IVE, Intravesical electrotherapy

IVU, Intravenous urography

J

Jaboulay (Winkelman) technique, 1845, 1847*f*

Jackson-Pratt drains, 148

Jehovah's Witnesses

- anesthesia preoperative considerations for, 448
- blood transfusion and, 133

Jejunal conduit, 3195–3196, 3196*t*

Jejunum, selection, 3162

JESS, Joint Expert Speciation System

Joint Expert Speciation System (JESS), 2010

Justice, definition of, 115

Juvenile granulosa cell tumors, 1120–1121

Juvenile nephronophthisis, 747*t*, 755–756, 756*f*, 756*b*

- clinical features of, 755–756
- evaluation of, 756, 756*f*
- genetics of, 755
- treatment of, 756

Juvenile xanthogranuloma, 883

Juxtaglomerular cell tumor, 2132

K

K antigens, 429

Kalicinski plication technique, for megaureter in children, 851, 851*f*

Kaposi sarcoma (KS)

- HIV and, 1267–1268, 1298–1299, 1300*f*
- as neoplastic condition, 1298–1299, 1300*f*
- of penis, 1742.e5

Karnofsky Performance Scale (KPS), 107, 107*t*

Karyotype, for male infertility, 1442

Kaye nephrostomy tamponade balloon, 178*f*

KDIGO, Kidney Disease: Improving Global Outcomes

Kegel's exercises, 2833

Kelly repair, for classic bladder exstrophy, 544

- continence outcomes with, 561
- technical aspects of, 549–550, 549*f*

Ketoconazole, 3677

Ketogenic diet, 449

Ketones, in urine, 19–20

Ketorolac, for urinary tract obstruction, 795

Kidney, 324*f*, 333–340, 333*f*–334*f*, 339*b*

- deterioration of, in urinary intestinal diversion, 3192–3193, 3193*b*
- early events in, 334
- molecular mechanisms of, 336

Kidney and retroperitoneum anterior approaches, 136–138, 138*f*, 139*t*

- Chevron and subcostal incision, 137–138, 139*f*
- thoracoabdominal incision, 136–137

Kidney cancer

- in geriatric patients, 2920.e13
- in nuclear medicine, 42

Kidney Disease: Improving Global Outcomes (KDIGO)

- AKI definition by, 1921, 1922*t*
- CKD classification by, 1927, 1928*f*

Kidney disease, nocturia and, 2665

Kidney infections, 1181*b*

- infectious granulomatous nephritis
  - malacoplakia, 1179–1181, 1180*f*
  - renal echinococcosis, 1181.e1, 1181.e2*f*
  - XGP, 1177–1179, 1178*f*–1179*f*
- renal infection (bacterial nephritis), 1166–1181
  - acute focal or multifocal bacterial nephritis, 1171.e1, 1171.e1*f*
  - for acute pyelonephritis, 1168–1171, 1168*f*–1169*f*, 1170*t*
  - bacterial “relapse,”, 1177.e1

    - chronic pyelonephritis, 1176–1177, 1177*f*
    - emphysematous pyelonephritis, 1171–1172, 1171*f*
    - infected hydronephrosis and pyonephrosis, 1174, 1174*f*
    - pathology, 1166–1168, 1167*f*–1168*f*
    - perinephric abscess, 1174–1176, 1175*f*
    - renal abscess, 1172–1174, 1172*f*–1173*f*

Kidney surgery, 2248–2278, 2278*b*

- approaches used in, 2248–2253
    - anterior, 2252–2253, 2253.e1*f*
    - dorsal lumbotomy, 2251, 2251*f*
    - flank, 2249–2251, 2249.e1*f*, 2250*f*–2251*f*, 2250.e1*f*, 2251.e1*f*
    - thoracoabdominal, 2251–2252, 2252*f*–2253*f*, 2252.e1*f*
- for benign diseases, 2253–2257
    - extracorporeal renal surgery, 2254–2257, 2256*f*
    - open nephrectomy, 2254, 2254.e1*f*
    - partial nephrectomy, 2254, 2255*f*
    - simple nephrectomy, 2253–2254, 2253.e2*f*, 2254*f*
- historical perspective, 2248
- for malignancy, 2257–2278
    - partial nephrectomy, 2261–2266, 2262*f*–2266*f*, 2263.e1*f*–2263.e2*f*, 2264.e1*f*
    - radical nephrectomy, 2257–2261, 2257*f*–2260*f*, 2258.e1*f*, 2259.e1*f*, 2260.e1*f*
    - vena caval thrombectomy, Vena caval thrombectomy
- preoperative evaluation and preparation for, 2248, 2248.e1*f*, 2249*f*
    - prophylactic measures, 2248
    - surgical instruments, 2248

Kidneys, 1865–1872, 1868*b*

- AAST Organ Injury Severity Scale for, 1992*t*
- anatomy of, 1865–1876
    - congenital anomalies in, 1869, 1869.e1*f*–1869.e2*f*
    - gross and microscopic, 1866–1868, 1866.e1*f*–1866.e2*f*, 1867*f*
    - innervation, 1872, 1872.e1*f*
    - lymphatic drainage, 1870–1871, 1870.e1*f*
    - radiologic, 1868–1869, 1868*f*, 1868.e1*f*, 1869*b*, 1869.e1*f*–1869.e2*f*
    - surface anatomy and relationships, 1865–1866, 1865.e1*f*–1865.e4*f*, 1866*f*
    - vasculature, 1869–1870, 1869.e2*f*–1869.e3*f*, 1870*f*–1871*f*, 1871*b*
- anatomy of, changes during pregnancy, 1185–1186, 1185*t*
- Ask-Upmark, 744, 744*f*
- cake or lump, 728*f*
- calcium absorption in, 2016
- collecting system of, 794

  cystic disease of, 741–775
  developing, pathological changes in, with urinary tract obstruction, 781–786
  disc, 728*f*
  drainage of, for urinary tract obstruction, 795
  ectopic
    inferior, 729
    superior, 728*f*, 729–731
  functional imaging of, 91–96
    ^{99}TC-MAG3 and ^{99}mTC-DTPA for, 92–93
    dosing and pharmacokinetics in, 92
    image acquisition and interpretation in, 92–93
    patient preparation for, 92
    relevant renal physiology of, 91–92
    Technetium-99m diethyltriaminepentaacetic acid (^{99}mTC-DTPA) for, 92
    Technetium-99m dimercaptosuccinic acid (^{99}mTC-DMSA) for, 92
    Technetium-99m mercaptoacetyltriglycine (^{99}mTC-MAG3) for, 92
  in genitourinary tuberculosis, 1308–1309
  growth regulation of, 783, 783*t*–784*t*
  horseshoe, 731–733, 733*b*
  localization, in UTI diagnosis, 1142.e1*t*, 1143
  L-shaped, 728*f*
  mature, pathological changes in, with urinary tract obstruction, 781, 782*f*
  organoneogenesis of
    molecular mechanisms of, 721
    new advances in, 714–715
  physical examination for, 10–12, 10*f*
  in prune-belly syndrome, 581, 582*f*
  sigmoid, 728*f*
  size of, with spina bifida, 629
  solitary, upper urinary tract calculi and, 2089
  supernumerary, 721–722, 722*f*–723*f*
  thoracic, 725–727, 726*f*
  urine egress from, in urinary tract obstruction, 794
Kidney-ureter-bladder (KUB) radiograph, kidney anatomy, 1868
King's Health Questionnaire, 111*t*
Kinins, urethral function effects of, 1902

Kisspeptin protein, 1392

Klinefelter syndrome and variants, 1000

Klippel-Trénaunay-Weber syndrome, 888

“The Knack, 2725, 2725.e1*t*

Kocher maneuver, for radical nephrectomy, 2258, 2258*f*

Kock ileal reservoir, for orthoptic urinary diversion, 3243–3244, 3244*f*

Kock pouch, 3213–3215, 3214*f*

KPS, Karnofsky Performance Scale

KS, Kaposi sarcoma

KUL-7211, ureteral response to, 1888–1889

L

LABD, Linear IgA bullous dermatosis

Labia majora, 1627.e1, 2435, 2436*f*–2437*f*

Labia minora, 1627.e1

Labial adhesions, 395, 396*f*, 986–987, 987*f*

Labioplasty, initial management, timing, and principles for, 1026, 1026*f*, 1028*f*–1029*f*

Labor, vesicovaginal fistulae with, 2925

Lactate dehydrogenase (LDH)

- in prostatic secretions, 3302
- in TGCTs, 1686

Lamina propria, 2462–2463

Laminectomy, LUT function and, 2620

Laparoendoscopic single-site surgery (LESS), 458, 466, 2419–2420

- access devices for, 212
- Boari flap, 3031
- instrumentation for, 218

- for kidney surgery
    - clinical experience of, 2305–2306, 2305*f*
    - robotic, 2306
    - surgical approaches and access for, 2284–2285, 2285*f*, 2286*t*
- pyeloplasty, for ureteropelvic junction obstruction, 1956–1957, 1957*f*

Laparoscopes, for laparoscopic and robotic surgery, 213, 213.e1*f*

Laparoscopic adrenalectomy, 2407–2409, 2407*b*

- left, 2414–2415, 2415*f*–2416*f*, 2417–2418
- outcomes, 2421–2423
- retroperitoneal approach, 2417–2418, 2418*f*, 2422
- right, 2415–2416, 2417*f*–2418*f*, 2418
- transperitoneal approach, 2414–2417, 2415*f*–2417*f*, 2422

Laparoscopic and robotic surgery, in children

- acid-base physiology during, 461
- advantages in postoperative pain control after, 459
- approach to, 465, 465*b*
    - retroperitoneal, 465
    - transperitoneal, 465
    - vesicoscopic, 465
- cardiovascular changes during, 460
- comparative effectiveness of access technique for, 465
- equipment and instrumentation for, 465–467, 468*b*
    - clips, 467
    - hemostatic devices, 466
    - laparoscopic ports, 465–466
    - robotic-assisted surgery, 467
    - single-site surgery, 466
    - staplers, 466
    - suture assistance, 467
- intracranial pressure during, 461
- learning curves for, 460
- minimally invasive surgery, 458–460
- open access for, 464, 464*f*
- pneumoperitoneum during
    - physiology of, 460–461, 462*b*
    - stress response to, 461
- principles of, 458–472

  - pulmonary changes during, 460–461
  - renal physiology during, 461
  - Veress needle access for, 463, 464*f*
  - visual obturator access for, 464–465
- Laparoscopic calicovesicostomy, for ureteropelvic junction obstruction, 1960
- Laparoscopic carts, 205, 205.e1*f*
- Laparoscopic colposuspension, 2759
- Laparoscopic dismembered tubularized flap pyeloplasty, for ureteropelvic junction obstruction, 1960
- Laparoscopic heminephrectomy, 2299
- Laparoscopic hysterectomy, ureteral injuries after, 1993
- Laparoscopic ILND, for penile cancer, 1761
- Laparoscopic kidney surgery, 2279–2308, 2308*b*
  - ablative techniques, 2304–2305, 2318
  - biopsy for medical renal disease, 2292, 2292*f*
  - calyceal diverticulectomy, 2294
  - complications of, 2306–2308, 2307*f*
  - laparoendoscopic single-site surgery
    - clinical experience of, 2305–2306, 2305*f*
    - robotic, 2306
    - surgical approaches and access for, 2284–2285, 2285*f*, 2286*t*
  - nephrolysis, 2294, 2294*f*
  - nephropexy, 2292–2294, 2293*f*
    - procedure for, 2293*f*
    - results of, 2293–2294
  - partial nephrectomy, Laparoscopic partial nephrectomy
  - patient evaluation and preparation for, 2279
  - radical nephrectomy, Laparoscopic radical nephrectomy
  - for renal cystic disease, 2291–2292, 2291*f*
    - procedure for, 2291, 2291*f*
    - results of, 2291–2292
  - simple nephrectomy, 2285–2291
    - dissection of ureter, 2287, 2287*f*
    - identification of renal hilum, 2287–2288, 2288*f*
    - organ entrapment and extraction, 2289, 2289*f*–2290*f*

- postoperative management for, 2289
- reflection of colon, 2285–2286, 2287*f*
- results of, 2291
- securing of renal blood vessels, 2288, 2288*f*
- upper pole dissection, 2288, 2288*f*

surgical approaches and access for, 2279–2285

- hand-assisted laparoscopy, 2281–2282, 2283*f*
- laparoendoscopic single-site surgery and natural orifice transluminal endoscopic surgery, 2284–2285, 2285*f*, 2286*t*
- retroperitoneal, 2279–2281, 2282*f*
- robotic-assisted laparoscopy, 2282–2284, 2284*f*–2285*f*
- transperitoneal, 2279, 2280*f*–2281*f*

Laparoscopic live-donor nephrectomy, 270

Laparoscopic partial nephrectomy (LPN), 2298–2304

indications for, 2298–2300, 2299*f*

- central and hilar tumors, 2299
- clinical stage T1b and greater tumors, 2299
- laparoscopic heminephrectomy, 2299
- multiple tumor management, 2300
- repeat, 2300
- tumors in solitary kidneys, 2299–2300

positive surgical margins in, 2304

procedure for, 2300–2304

- collecting system repair, 2302, 2303*f*
- hemostasis, 2301–2302, 2302*f*
- renal hypothermia, 2302
- retroperitoneal approach, 2300
- robotic-assisted, 2300
- transperitoneal approach, 2300
- tumor localization and excision, 2300–2301, 2301*f*
- warm ischemia and hilar control, 2303–2304

results of, 2304

Laparoscopic Prostatectomy Robot Open (LAPPRO) study, 3581

Laparoscopic pyelolithotomy, for pediatric kidney stone disease, 868–870

Laparoscopic pyeloplasty

technique of, 832–834, 833*f*

for ureteropelvic junction obstruction

- anterior extraperitoneal approach to, 1956
- in children, 830–834, 833*f*–834*f*
- with concomitant pyelolithotomy, 1958–1960
- dismembered tubularized flap for, 1960

    - indications and contraindications for, 1955
    - results of, 1957–1958, 1959*t*
  - retroperitoneal approach to, 1956
  - robotic-assisted, 1956, 1957*f*
  - single-site surgery approach, 1956–1957
  - techniques for, 1955–1957
  - transmesenteric modification of transperitoneal approach to, 1956
  - transperitoneal approach to, 1955–1956, 1955*f*
  - vascular transposition for, 1956

Laparoscopic radical nephrectomy (LRN), 2294–2298
- hand-assisted, 2296–2297, 2296*f*
- retroperitoneal approach to, 2295–2296
- special considerations for, 2297–2298
  - cytoreductive nephrectomy, 2298
  - en bloc hilar vessel stapling, 2297
  - large tumors, 2297
  - local recurrence, 2298, 2298*f*
  - lymphadenectomy, 2297–2298
  - port-site recurrence, 2297
  - renal vein and caval tumor thrombus, 2298
  - specimen extraction, 2297
  - surgical salvage after failed ablative therapies, 2298
  - tumor seeding, 2297
- transperitoneal approach to, 2294–2295, 2295*f*

Laparoscopic radical nephroureterectomy, for UTUC, 2202–2205
- indications of, 2202
- results of, 2205
- robot-assisted, 2205, 2205*f*
- transperitoneal laparoscopic nephroureterectomy, 2203–2204, 2203*f*–2204*f*

Laparoscopic radical prostatectomy (LRP)
- abdominal access in, 3570, 3571*f*
- anesthesia for, 3568–3570
- apical dissection, 3576–3577, 3577*f*
- bladder neck in, identification and transection of, 3573, 3573*f*
- bladder neck reconstruction, 3577
- blood loss/transfusion with, 3580
- bowel preparation for, 3567
- contraindications for, 3566–3567

deep dorsal venous complex litigation in, 3572–3573, 3573*f*

evolution of, 3566

extraperitoneal approach to, 3570–3571, 3571*f*

  transperitoneal approach *versus*, 3571

hospital stay with, 3581

indications for, 3566–3567

informed consent for, 3567–3568

instrumentation for, 3567, 3568*b*, 3570*b*

insufflation in, 3570, 3571*f*

intraoperative inspection of prostate, 3577

neurovascular bundle preservation in, 3575–3576, 3575*f*–3576*f*

operating room personnel for, 3568, 3569*f*

outcomes with, functional, 3581–3583

pain management, 3578–3579

patient positioning for, 3568, 3569*f*

patient selection for, 3566–3567, 3570*b*

postoperative complications of, 3580–3581

postoperative management for, 3578–3580

preoperative preparation for, 3567–3570, 3570*b*

prostate and rectum plane development in, 3574–3575, 3574*f*

prostatic pedicle control in, 3575, 3575*f*

return to normal activity, 3579

robotic-assisted *versus*, 3570

role of continence physiotherapy in, 3579

seminal vesicle dissection in, 3573–3574, 3574*f*

space of Retzius development for, 3571–3572, 3572*f*

specimens

  delivery in, 3578

  entrapment in, 3577

technique of, 3578*b*

transperitoneal approach to, 3570

  extraperitoneal approach *versus*, 3571

trocar placement in, 3570, 3571*f*

vasa deferentia dissection in, 3573–3574, 3574*f*

vesicourethral anastomosis, 3577–3578, 3578*f*

  posterior support of, 3577, 3578*f*

Laparoscopic removal, of kidney down to mid-ureter, 2203–2204, 2203*f*–2204*f*

Laparoscopic retroperitoneal lymph node dissection, for testicular tumors, 1734–1741, 1741*b*

- bilateral, 1738
- complications of, 1739–1740, 1739*t*
- duplication of, 1735
- postoperative care after, 1738–1739
- prospective nerve-sparing techniques for, 1739
- rationale and evolution of, 1734
- results and current status of, 1740–1741, 1740*t*
- staging, 1734–1735
- surgical technique for, 1735–1738
    - approach for, 1735
    - left-sided dissection, 1736–1738
    - patient positioning and port placement for, 1735–1736, 1735*f*–1736*f*
    - right-sided dissection, 1736, 1736*f*

Laparoscopic retropubic suspension surgery, 2768–2769, 2769*b*

Laparoscopic sacrocolpopexy, for apical pelvic organ prolapse repair, 2802*f*–2803*f*, 2803–2804

Laparoscopic surgery, 145

- access technology for hand-assist devices, 212, 212*f*
    - trocars, 211, 211*f*
- common urologic procedures, antimicrobial prophylaxis for, 1199–1200
- complications and troubleshooting, 223–231, 232*b*
    - anesthesia-related, 228
    - early postoperative, 230–231
    - equipment-related, 223–224
    - exit-related, 230
    - late postoperative, 231
    - during learning curve, 223
    - pneumoperitoneum-related, 224
    - of seminal vesicle surgery, 1864
- equipment placement for, 205–207, 205.e1*f*
- instrumentation used in
    - for da Vinci Robotic System, 218, 218*f*
    - for grasping and blunt dissection, 218
    - for incising and hemostasis, 214–215

  - for LESS, 218
  - for morcellation, 218
  - for NOTES, 218
  - for port site closure, 219
  - for retraction, 218
  - for specimen entrapment, 217–218, 217*f*
  - for stapling and clipping, 216–217, 216*f*
  - surgical pharmaceuticals, 215
  - for suturing and tissue anastomosis, 215–216, 215.e3*f*
  - for visualization, 213, 213.e1*f*
- operative team placement for
  - retroperitoneal upper abdominal procedures, 207, 207*f*
  - transperitoneal upper abdominal procedures, 206, 206*f*
- for partial nephrectomy, 811–813, 814*f*
- physiologic considerations in, 223*b*
  - hemodynamic effects related to approach and patient position, 222
  - hormonal and metabolic effects during surgery, 222–223
  - immunologic effects, 223
  - insufflant choice, 220
  - pneumoperitoneum pressure choice, 220
- preoperative preparation for, 204*b*
  - blood products, 204
  - bowel preparation, 204
  - operating room setup, 205, 205*b*
  - patient positioning, 205*f*
  - patient selection and contraindications, 203–204
  - prophylaxis, 205
- procedure for, 219*b*
  - abdomen exit, 218–219
  - achieving extraperitoneal access and developing extraperitoneal space, 210–211
  - achieving retroperitoneal access and developing retroperitoneal space, 209–210
  - achieving transperitoneal access and establishing pneumoperitoneum, 209
  - hand-assist device placement, 212
  - initial incision, 207
  - port removal and fascial closure, 218–219
  - port site closure, 219
  - skin closure, 219
  - trocar placement, 212–213
- training and practicing for, 231–233
  - equipment for, 232
  - formal programs for, 233
- ureteral injuries with, 1993

Laparoscopic training boxes, 232, 232*f*, 232.e1*f*

Laparoscopic ureterocalicostomy, for ureteropelvic junction obstruction, 1958

Laparoscopic ureterolysis, for retroperitoneal fibrosis, 1980

Laparoscopic ureteroneocystostomy, for ureteral stricture disease, 1972, 1972*f*

- with Boari flap, 1973
- with psoas hitch, 1972–1973

Laparoscopic ureteroureterostomy, for ureteral stricture disease, 1972

Lapides classification, of voiding dysfunction, 2522–2523, 2522*b*

Lapides Diagnostic Foley catheter, 154

Lapra-Ty clips, 215, 215*f*

Laser ablation, for penile cancer, 1752

Laser cystolithotripsy, 244.e4

Laser instrumentation

- for laparoscopic and robotic surgery, 214
- for tissue dissection and cauterization
  - CO2 laser, 241
  - delivery systems for, 238–241
  - diode laser, 240
  - Ho:YAG laser, 240
  - KTP laser, 239
  - LBO laser, 239–240
  - light-tissue interaction, 238–239
  - Nd:YAG laser, 239
  - pulsed and continuous wave lasers, 238
  - soft tissue applications, 238–241
  - Thu:YAG laser, 240–241

Laser lithotripsy, 2110–2111

- Ho:YAG and Er:YAG,basic physics of, 244

Laser treatments, for benign prostatic hyperplasia, 3435–3438, 3443*b*

- safety for, 3435–3436

Lasers, for urethral stricture disease, 1818–1828

Late-night salivary cortisol, in evaluation of adrenal masses, 2400

Late relapse RPLND, 1728*t*, 1729

Latent pacemakers, ureteral, 1882

Latent stress incontinence, 2563

Latent syphilis, 1257–1258

Lateral cutaneous nerve, 136*f*

Lateral decubitus position, 146

Lateral defect, in pelvic floor support mechanism, 2597–2598

Lateral fusion abnormalities, 985–986, 985*f*

- inguinal hernias, 988
- rhabdomyosarcoma, 986, 986*f*
- uterus and cervix duplication, 985–986, 986*f*

Lateral plexuses, 2452

Lateral resolution, of ultrasonography images, 70, 70*f*

Lax suspensory ligament, penile implants and, 1596, 1596*f*

Laxative abuse, ammonium acid urate stones from, 2032

LDH, Lactate dehydrogenase

Le Duc technique, in urinary diversion, 3189, 3189*f*

Leadbetter and Clarke technique, in urinary diversion, 3185, 3185*f*, 3186*t*

Lead-time bias, 102, 103*f*

Leak point pressures, urodynamic studies of, 2561–2563

- abdominal, 2561, 2562*f*
- detrusor, 2561*f*, 2562

Left adrenalectomy

- laparoscopic, 2414–2415, 2415*f*–2416*f*, 2417–2418
- open, 2412–2413, 2412*f*–2413*f*

Leiomyoma

- bladder, 3038, 3039*f*
- renal, 2131, 2131*f*, 2131*b*
- of urethra, 1776

Leiomyosarcoma
    of kidney, 2181
    retroperitoneal tumors and, 2231, 2231*f*
Length-time bias, 103, 103*f*
Lentigo simplex, 1304, 1305*f*
Lenvatinib, for RCC, 2337–2338
Leptin, 1392
    in prostate cancer, 3463
Lesion
    measurable, 104
    target, 104–105
LESS, Laparoendoscopic single-site surgery
Leucine aminopeptidase, in prostatic secretions, 3302
Leukemia
    of kidney, 2181–2183, 2182*t*
    testicular metastases of, 1124–1125, 1709
Leukocyte esterase, 437
    in urine, 20–21, 20*f*
Leukoplakia, of bladder, 3082
Levator ani muscle, 2430–2432, 2432*f*
    complex, 2597
Levator plate, 2430–2432, 2432*f*
Leydig cell aplasia, 1011
Leydig cell tumors, 1124, 1124*f*, 1707–1708
Leydig cells, 305, 1370
    testis cytoarchitecture and, 1394
    testosterone production by, 3280–3281
    testosterone synthesis in, 1394
        control of, 1395–1396
LGPIN, Low-grade prostatic intraepithelial neoplasia

LGV, Lymphogranuloma venereum

LH, Luteinizing hormone

Libido, loss of

- hormonal therapy and, 3681
- patient history of, 6

Lichen nitidus (LN), as papulosquamous disorder, 1281

Lichen planus (LP), as papulosquamous disorder, 1280–1281, 1281*f*

Lichen sclerosus (LS)

- male, 1742.e1–1742.e2
  - reconstructive surgery for, 1808–1810, 1809*f*
- as papulosquamous disorder, 1281–1282, 1282*f*

Lichen sclerosus et atrophicus, in male, circumcision and, 875, 876*f*

Lidocaine, for cystourethroscopy, 189–190

Lifestyle modifications

- for ED, 1529
- for urinary incontinence, 2732–2734
  - bowel function, 2734
  - caffeine reduction, 2733
  - dietary irritants, 2733–2734
  - fluid management, 2732–2733
  - levels of evidence and recommendations, 2722.e1*b*
  - obesity and weight reduction, 2734

Ligaments, of female pelvis, 2428–2430, 2430*f*–2432*f*

Ligand-binding domain, of androgen receptors, 3290–3291

LigaSure device, 466

LigaSure vessel-sealing system, 214

Ligation, of ureter, 2000–2001, 2001*f*

Light-tissue interaction, 238–239, 239*f*

Likelihood ratio (LR), 3479–3480

Likert scales, 108–109

Linea alba, 2444, 2447*f*–2448*f*

Linear IgA bullous dermatosis (LABD), 1285, 1285*f*

Linear-quadratic formula, 3593

Lipomeningocele, 639–641, 642*b*

- pathogenesis of, 639–641, 641*f*
- presentation of, 639, 639*t*, 640*f*–641*f*
- recommendations for, 641, 642*f*

Lipopolysaccharide (LPS), 1138

Liposarcoma

- of kidney, 2181
- retroperitoneal tumors and, 2229–2230, 2230*f*
- of testicular adnexa, 1709

Lipotoxicity, 2028–2029

Lithium triborate (LBO) laser, 239–240

LithoClast Ultra, 244–245

Lithotomy position, 146

Lithotripsy

- dual-modality, 244–246, 245*f*
- holmium:YAG and Erbium: YAG laser, 244
- intracorporeal, 2109–2113
  - ballistic lithotripsy, 2111–2112, 2112*f*
  - combination ballistic and ultrasonic devices in, 2112–2113
  - electrohydraulic lithotripsy, 2109–2110, 2110*f*
  - laser lithotripsy, 2110–2111
  - ultrasonic lithotripsy, 2112, 2112*f*
- pneumatic, 243, 243*b*
  - basic physics of, 243
  - tissue effects, 243
- ultrasonic, 243, 244*b*
  - basic physics of, 243
  - tissue effects of, 243

Live animal models, laparoscopic training with, 232

Liver cirrhosis, benign prostatic hyperplasia and, 3322

Liver injury, during radical nephrectomy, 2261

LN, Lichen nitidus

Localization, in UTI diagnosis, 1142.e1*t*, 1143

Localized prostate cancer

- active management strategies for, 3522–3536
- androgen deprivation therapy for, 3683–3684
- host evaluation of, 3522–3529
  - bladder function, 3524
  - bowel function and other conditions affecting treatment choice, 3525
  - longevity assessment and competing risks for mortality, 3522–3524, 3523*f*
  - patient preference and biases, 3525
  - sexual function, 3524–3525
- patient counseling of, 3532–3535, 3532*f*
  - observation *versus* active treatment, 3532–3534, 3533*t*–3534*t*
  - partial gland *versus* whole gland treatment, 3534–3535
  - surgery *versus* radiation *versus* whole-gland ablation, 3535
  - treatment delivery type, 3535
- risk assessment of, 3525–3529
  - Epstein criteria, 3526–3527
  - genomic tests for risk stratification, 3529
  - Gleason scoring and grade groups, 3526
  - low, intermediate, and high risk definition, 3525–3526, 3526*t*
  - nomograms for prediction of stage, 3527–3528
  - prostate magnetic resonance imaging in, 3528–3529
  - staging, 3527
  - stratification nomograms, 3528, 3528*f*
  - tools for risk stratification, 3525
- treatment selection of, 3529–3532
  - comparative population-based studies, 3529–3531, 3530*f*
  - functional outcomes, 3531–3532
  - oncologic outcomes, 3529–3532

Locally advanced prostate cancer

- androgen deprivation for, 3655–3656, 3656*b*
  - intermittent, 3656
  - quality of life, 3656
- clinical trials for, 3657, 3657*t*–3658*t*
- contemporary risk assessment for, 3640–3641, 3640*b*
- definition of, 3640–3643
- focal ablative therapy for, 3655
  - cryoablation, 3655

        - high-intensity focused ultrasound, 3655
    - imaging modalities for, 3641–3642, 3641*f*–3642*f*
    - immediate *versus* delayed ADT in, 3684
    - incidence trends of, 3643–3644, 3643*b*
    - management of delayed sequelae, 3657
    - natural history of, 3644–3645, 3645*f*, 3645*t*
    - novel markers for, 3642–3643, 3642*t*
    - radiation therapy for, 3652–3655, 3653*t*
        - adjuvant androgen deprivation with, 3653–3654
        - chemotherapy with, 3654–3655
        - neoadjuvant androgen deprivation with, 3652–3653, 3654*b*
    - radical prostatectomy for, 3645–3652, 3648*b*
        - adjuvant androgen deprivation with, 3652
        - adjuvant radiation therapy, 3650–3652, 3651*t*, 3652*b*
        - for clinical stage T3, 3645–3652, 3646*t*
        - neoadjuvant androgen deprivation, 3648–3649, 3648*t*–3649*t*
        - neoadjuvant chemotherapy and chemotherapy-hormonal therapy, 3649–3650, 3650*t*
        - outcomes of, 3646–3647, 3647*f*
        - pathologic findings in, 3643, 3643*t*
    - treatment, 3640–3658
        - trends of, 3643–3644, 3643*b*, 3644*f*

LOCM, Low-osmolality contrast media

Loop diuretics, in stone formation, 2033
    - surgical management of, 2077.e3

Loop end ileostomy, 3183, 3183*f*

Loopography, 38, 39*f*

Lord plication, 1845, 1847*f*

Lost stone, in ureteroscopic stone management, 2109

Low-dose continuous prophylaxis, for recurrent UTIs, 1162–1163

Low-dose rate brachytherapy, 1765–1767
    - for prostate cancer, 3596, 3597*f*

Lower extremity compartment syndrome, 262, 263*f*

Lower motor neuron (LMN) lesion, voiding dysfunction after, 2522, 2523*b*

Lower pole renal calculi, surgical management of, 2081–2084, 2081*f*, 2082*t*, 2083*f*

Lower tract endoscopy
- antimicrobial prophylaxis for, 1198
- cystoscopy, antimicrobial prophylaxis for, 1198

Lower tract urinary complications, 267–269
- bladder injuries, 267
- urine leaks, after radical prostatectomy, 267–269, 268*f*–269*f*

Lower urinary system, aging and, 2906

Lower urinary tract, assessment of, 503–505
- cystographic imaging, 503–504, 504*f*
- cystoscopy and the positioning of the instillation of contrast cystogram, 504–505

Lower urinary tract (LUT)
- afferent pathways in, 2481–2486, 2487*b*
  - cannabinoids, 2486
  - functional properties of, 2482–2483, 2483*f*
  - modulators of, 2483–2484
  - nitric oxide in, 2484, 2484*f*
  - pelvic organ interactions with, 2486, 2486*f*
  - properties of, 2481
  - purinergic signaling, 2484–2485, 2485*f*
  - spinal cord pathways of, 2481–2482, 2481*t*, 2482*f*
  - transient receptor potential cation channels, 2485
- anatomy of, 2461, 2462*f*
  - bladder, Bladder, anatomy of
  - urethra, Urethra, anatomy of
- efferent pathways of, 2487–2493, 2487*f*, 2489*f*–2492*f*, 2490*b*, 2491*t*
- electrical stimulation of, techniques of, 2747–2754
  - dorsal genital nerve, 2752
  - intravesical, 2747–2748
  - percutaneous tibial nerve, 2748–2751, 2749*f*
  - pudendal nerve, 2751–2752
  - sacral nerve, 2752–2754
  - transcutaneous, 2748
- function of, 2679
  - mechanisms underlying two phases of, 2514
  - normal, 2514–2516
  - sensory aspects of, 2516
  - two-phase concept of, 2514–2516

- neural control of, 2480–2497, 2593
  - parasympathetic pathways, 2480, 2480*f*
  - peripheral nervous system, 2480–2497, 2480*f*
  - somatic pathways, 2480*f*–2481*f*, 2481
  - supraspinal pathways, 2493–2497, 2495*f*–2496*f*
  - sympathetic pathways, 2480, 2480*f*
- overview of, 2580
- pharmacology of, 2497–2503
  - adrenergic mechanisms, 2500–2501, 2501*f*, 2501*b*
  - afferent neuropeptides, 2501–2502, 2501*t*
  - muscarinic mechanisms, 2497–2500, 2499*t*, 2500*b*
  - sex steroids, 2502–2503
  - urethral tone in women, 2501
- posterior urethral valves and, 603–604, 605*f*–606*f*
- supraspinal pathways in, 2493–2497
  - additional regions in, 2496–2497
  - bladder modulatory mechanisms, 2493–2494, 2495*f*
  - brain-bladder control model, 2497, 2498*f*
  - central circuitry regulation of, 2494–2495
  - cerebral control of voiding, 2496
  - human brain imaging studies in, 2496, 2496*f*
  - modulators in, 2495–2496
  - neurotransmitters in, 2495–2496
  - pontine micturition center, 2493–2494, 2495*f*
- transabdominal pelvic ultrasonography of, 80–81, 80*f*, 82*f*
- trauma and, 2527

Lower urinary tract calculi, 2114–2120, 2120*b*
- bladder calculi
  - after renal transplantation, 2117
  - bladder outlet obstruction with bladder lithiasis, 2115–2116
  - etiopathogenesis of, 2114–2115
  - in patients with spinal cord injury, 2116–2117
  - in urinary diversions and augmented bladder, 2116
- bladder stones
  - endourologic approach to, 2115, 2116*f*
  - management of, 2115
  - open surgery for, 2115
  - presentation of, 2115
- history of, 2114
- in special situations, 2115–2117
- unusual, 2118–2120

- preputial calculi, 2118–2119
- prostatic calculi, 2119–2120, 2119*f*

urethral calculi, 2117–2120

- clinical presentation and evaluation of, 2117–2118
- pathogenesis and composition of, 2117
- primary, 2117
- treatment of, 2118, 2119*f*

Lower urinary tract catheterization, 152–159, 159*b*

complications of, 158–159

- erosion, 159
- iatrogenic trauma, 159
- infection, 158–159, 159*b*
- malignancy, 159
- stricture, 159

contraindications of, 152

diagnostic, 152

difficulty with, 156–158, 158*f*

- abnormal anatomy, 157–158
- artificial urinary sphincter, 158
- bladder neck reconstruction, 158
- bladder replacement, 157
- continent urinary reservoir, 157–158
- obesity, 157
- posterior urethral valves, 157
- prostatic obstruction, 156–157
- reconstruction of, 157
- urethral stricture, 157

LRP, Laparoscopic radical prostatectomy

LS, Lichen sclerosus

L-shaped kidney, 728*f*, 729

Lumbar notch, 169, 170*f*

Lumbar vein, 1869–1870

Lumbodorsal fascia, in retroperitoneum, 1665–1666, 1666*f*, 1666.e1*f*

Lumbosacral plexus, 1675–1676, 1675.e1*f*, 1677*f*–1678*f*, 1679*t*, 2447*f*–2448*f*, 2453, 2453*f*, 2453*t*

Lumbosacral trunk, 2453*t*

Luminal epithelial cells, 3278, 3278*f*

Lungs

- development of, amniotic fluid and, 716–717
- in prune-belly syndrome, 586–587

LUT, Lower urinary tract

LUTD, Lower urinary tract dysfunction

Luteinizing hormone (LH), 1390, 1391*f*, 1395–1396, 1429, 1437

Luteinizing hormone receptor abnormality, 1011

Luteinizing hormone-releasing hormone agonists, 3676

Luteinizing hormone-releasing hormone antagonists, 3676–3677

LUTS, Lower urinary tract symptoms

LVI, Lymphovascular invasion

17,20-Lyase deficiency, 1012

Lycopene, for benign prostatic hyperplasia, 3398–3399

Lyme disease, lower urinary tract dysfunction and, 2624

Lymph node metastases, 3511

Lymph node-positive, treatment of, 2222–2224, 2223*f*

Lymph nodes

- counts, RPLND outcomes and, 1729
- iliac, 2433
- number of identified, 3116–3117, 3116*f*

Lymphadenectomy
- common iliac, 3152, 3153*f*–3154*f*
- external iliac, 3148–3149, 3151*f*
- hypogastric, 3149–3152, 3153*f*
- inguinal
  - antibiotics for, 1801
  - anticoagulation for, 1801
  - bed rest in, 1801
  - complications of, 1801–1802
  - compressive dressings and stockings for, 1801
  - dietary considerations of, 1801
  - drainage, 1801
  - postoperative care after, 1801
- laparoscopic radical nephrectomy with, 2297–2298
- obturator, 3149, 3152*f*
- patient positioning and port placement for, 1736, 1737*f*–1738*f*
- presacral, 3152, 3154*f*
- for RCC, 2177, 2177*f*, 2260, 2260*f*, 2260.e1*f*
- in retropubic radical prostatectomy, 3551–3552, 3551*f*
- for UTUC, 2205–2207, 2206*f*

Lymphangiomas, renal, 2132

Lymphatic complications, after RPLND, 2244

Lymphatic drainage
- of bladder, 2456
- of kidneys, 1870–1871, 1870.e1*f*
- of pelvis
  - female, 2433, 2434*f*
  - male, 2452–2453
- of retroperitoneum, 1674, 1675*f*
- of ureters, 1870–1871, 1870.e1*f*
- of uterus, 2436–2437
- of vulva, 2436

Lymphatic spread

of infection, 1131.e1

of UTUC, 2193–2194

Lymphedema

as filariasis clinical manifestation, 1329

genital, 884–885

Lymphocele, 280–281, 280*t*, 281*f*, 1938–1939
  after RPLND, 1731, 2244
  diagnosis of, 1939
  laparoscopic and robotic surgery causing, 231.e1
  treatment of, 1939
Lymphogranuloma venereum (LGV), 1255*t*, 1260–1261, 1260*f*
Lymphoma
  of kidney, 2181–2183, 2182*t*
  prostatic, 3513
  retroperitoneal tumors and, 2236, 2237*f*
  testicular metastases of, 1124–1125, 1709
Lymphovascular invasion (LVI), UTUC with, 2197

M

M inverted V glansplasty (MIV), 920, 922*f*
M region, 2493
MACE, Malone antegrade continence enema
Machado-Joseph (MJ) disease, lower urinary tract dysfunction and, 2632
Macrohematuria, 247
Magnesium
  in calcium stone formation, 2017
  in crystal formation, 2014
  metabolism of, 2016
  transport of, urinary tract obstruction and, 794
Magnetic resonance angiography (MRA), for renovascular hypertension screening, 1917–1918, 1918*b*
Magnetic resonance fusion-guided prostate biopsy, 66–67
Magnetic resonance imaging (MRI), 51–67, 61*t*, 67*b*, 390, 412–415
  of acute scrotum, 414
  adrenal, 51–54

of adrenal glands, 2352
for adrenal mass evaluation, 2395–2396
for biochemical recurrence after radical prostatectomy, 3662
of bladder RMS, 1113
of bladder/urethra, 414
cranial, 1444–1445, 1445*f*
of cyst/masses/stones, 413–414
for differences of sex development, 415
and ED, 1528
of epididymis, 1375–1376
of female pelvis, 2440–2442, 2440*f*–2442*f*
fundamentals of, 412–413
for genitourinary tuberculosis diagnosis, 1313
for infection, 414
for inguinal node dissection, 1792
of IVC tumor thrombus, 2175
of kidney/ureter, 413–414, 1866.e2*f*
    hydronephrosis, 413
for locally advanced prostate cancer, 3641, 3641*f*
of male pelvis, 2458–2460, 2459*f*–2460*f*
with nanotechnology, for inguinal node dissection, 1792
for neuroblastoma, 1089, 1089*f*–1090*f*
for other congenital malformations, 414
for pelvic organ prolapse, 2589*f*, 2597
of penis, 1386, 1388*f*
of posterior urethral valves, 607, 608*f*
in pregnant, 284
of prostate, 61–63, 1380–1381, 1381*f*
    for localized prostate cancer, 3527–3529
for prostate cancer, 3542–3543, 3543*b*
protocol of, 412–413
for radiation therapy for prostate cancer, 3590–3591
renal, 390
of renal calculi, pretreatment assessment, 2071
for renal tumor ablation, 2313, 2314*f*
for renal tumor evaluation, 2135, 2138*f*

  - for retroperitoneal fibrosis, 1979, 1979*f*
  - for sedation in child, 413
  - of seminal vesicles and ejaculatory ducts, 1378, 1378*f*
  - of testis, 1373–1374
  - for TGCTs, 1686
  - for undescended testis, 415
  - for ureteral anomalies, 805, 805*f*–806*f*
  - for urethral diverticula, 2983, 2985*f*

        perineum, 2450*f*–2451*f*, 2451*b*
        perineum and perineal body fasciae, 2449–2450, 2450*f*–2451*f*
        rectum, 2450*f*, 2454, 2455*f*
        soft tissues of, 2448–2449, 2449*f*
        urethra, 2465, 2465*f*
        vasculature of, 2451–2452, 2451*t*
        venous supply, 2452
        viscera, 2454–2456, 2457*b*
    endoscopic anatomy of, 2456–2457, 2457*f*, 2460*b*
        CT, 2458, 2458*f*–2459*f*
        magnetic resonance imaging, 2458–2460, 2460*f*
        radiographs and fluoroscopy, 2457–2458
Male reproductive system
    pediatric tumors of, paratesticular RMS, 1126–1127, 1127*b*
    physiology of, 1390–1410
        ductus (vas) deferens, 1406–1407
        seminal vesicle and ejaculatory ducts, 1407–1408
        testis, 1392–1394, 1393*f*–1394*f*
Male reproductive system anatomy
    epididymis, 1374, 1374*f*–1376*f*, 1376*b*
    penis, 1383–1386, 1387*b*, 1807, 1807.e1*f*–1807.e7*f*
    prostate, 1378–1381, 1379*f*–1381*f*, 1381*b*
    scrotum, 1387–1389, 1388*f*, 1389*b*
    seminal vesicles and ejaculatory ducts, 1377–1378, 1378*f*, 1378*b*

- testis, 1370–1374, 1371*f*–1373*f*, 1374*b*
- urethra, 1381–1383, 1381*f*–1384*f*, 1384*b*, 1807, 1807.e1*f*–1807.e7*f*, 2465, 2465*f*
- vas deferens, 1376–1377, 1376*f*–1377*f*, 1377*b*

Male stress incontinence, 3009

Male stress urinary incontinence, injectable agents for, 2896–2897

- after urinary diversion, 2897–2898
- injection techniques, 2896–2897

Male urethra, 152

- catheterization of, 153

Male urethral cancer, 1776–1782, 1782*b*

- anterior, 1777–1781
- carcinoma of penile urethra, 1778–1780, 1779*f*–1780*f*
- epidemiology, etiology, and clinical presentation of, 1776–1777
- evaluation and staging of, 1777, 1778*f*, 1778*t*
- pathology of, 1777, 1777*f*, 1777*t*
- posterior, 1781–1782, 1782*t*
- recurrence after cystectomy, 1786*t*, 1789*b*
- treatment of, 1778, 1779*t*

Malecot catheters, 155, 155*f*, 173, 174*f*

Male-to-female transexuals, Transwomen

Malignancy, PC-RPLND findings of, survival outcomes associated with, 1726–1727, 1727*t*

Malignancy-associated hypercalcemia, 2020

Malignant fibrous histiocytoma/undifferentiated pleomorphic sarcoma, retroperitoneal tumors and, 2231, 2232*f*

Malignant lesions

- adrenal, 2384–2388
    - adrenal cortical carcinoma, 2384–2388, 2384*f*, 2385*t*, 2386*f*, 2386*b*, 2387*t*, 2388*b*
    - malignant pheochromocytomas, 2373, 2375, 2389
    - metastases, 2388–2389, 2389*f*, 2390*b*
    - neuroblastoma, Neuroblastoma
- of bladder, 3083–3084, 3083*f*–3084*f*

Malignant peripheral nerve sheath tumors, in retroperitoneum, 2235–2236

Malignant pheochromocytomas, 2373, 2375, 2389

Malone antegrade continence enema (MACE), 673, 674*f*–675*f*, 678*t*

Malrotation, of kidney, 1869, 1869.e1*f*

Mammalian target of rapamycin (mTOR)

- inhibitors, for metastatic RCC, 2326–2327, 2338–2339, 2340*f*, 2340*t*
- in RCC, 2145, 2145*t*

Management principles, of ED

- cardiac risk assessment, 1516–1517, 1517*f*
- early detection, 1515, 1515*t*
- follow-up care, 1517
- goal-directed management, 1516
- role of partner interview, 1516
- shared decision making and treatment planning, 1515–1516
- specialist referral, 1517
- step-care approach, 1516

Manchester procedure, in uterine sparing, 2816–2817, 2819*t*

Mannose-sensitive adhesin, 429

Manometry, for PFM activity measurement, 2729

Manual dexterity, orthoptic urinary diversion and, 3238

Manual dilation, for achieving retroperitoneal access and developing retroperitoneal space, 210

Manual therapy, for genito-pelvic pain-penetration disorder, 1653

Margins, 3511

Marionette stitch, for minimally invasive urinary diversion, 3261–3262, 3261*f*

Marshall-Marchetti-Krantz (MMK) procedure, 2762–2763, 2763*b*

- Burch colposuspension *versus*, 2773
- results with, 2762–2763
- technique for, 2762, 2762*f*

Martius flap

- in urethrovaginal fistulae, 2950
- in vesicovaginal fistula repair, 2940, 2949*f*

Martius labial fat pad graft, 2866–2868

Masked hypertension, 352

Mast cells, in BPS/IC etiology, 1232.e4–1232.e5, 1232.e5*b*

Mastectomy, 3063–3064

Maternal anemia, from bacteriuria in pregnancy, 1186.e1

Maternal-fetal ultrasound, 358, 359*f*

Matrix

- of bladder wall, 2464
- renal calculi and, 2015

Matrix GLA protein (MGP), in crystal formation, 2015

Matrix stones

- composition of, 2076–2077, 2076*f*
- imaging of, 2076, 2076*f*
- in renal calculi, 2032

Matrix substance A, 2015

Maturation arrest, 1445.e1, 1445.e2*f*

Maximum birth weight, pelvic organ prolapse and, 2591

Maximum urethral closure pressure (MUCP), 2563, 2757

- for sling procedure, 2831, 2833

Maximum urethral pressure (MUP), 2563

Maximum voided volume (MVV), 2667

Mayer-Rokitansky-Küster-Hauser syndrome (MRKH), 720, 1017

McCall culdoplasty technique, vaginal hysterectomy with, 2814–2815, 2815*f*

MCDK, Multicystic dysplastic kidney

McGuire's technique, for pubovaginal sling, modified, 2834

MCKD, Medullary cystic kidney disease

MDSC, Microsurgical denervation of the spermatic cord

Meatal advancement glanuloplasty (MAGPI), 920, 921*f*

Meatal retrusion, 938

Meatal stenosis, 875, 875*f*, 937–938

- urethral, reconstructive surgery for, 1811

Meatotomy, urethral reconstruction and, 3071

Mechanical assistants, for laparoscopic and robotic surgery, 218.e2

Mechanical bowel preparation, in urologic surgery, 125

Mechanical index (MI), in ultrasonography, 78

Mechanical injury, during laparoscopic and robotic surgery, 229

Mechanical properties, of ureters, 1890–1891

- force-length relations, 1890, 1890*f*
- force-velocity relations, 1890–1891, 1891*f*
- pressure-length-diameter relations, 1891

Mechanical reliability, repair for, 1597, 1597*f*

Medial fibroplasia, 1915, 1915*f*

Medial hyperplasia, 1916

Median raphe cysts, 882, 882*f*, 1304

Median umbilical ligament, 330–333

Medical conditions

- in bladder tumor, 3076–3077
- urinary incontinence and, 2586

Medical devices, in ED, 1536–1537

Medical ethics, 115–116, 118*b*

- in clinical practice, 115–116
- four-principles of, 115
- history of, 115

Medical expulsive therapy (MET), for ureteral calculi

- in megaureter, 2087

  stone localization and, 2085

Medical history, adrenal surgery and, 2407–2408

Medical indications, 116

Medical management, in schistosomiasis treatment, 1326–1327

Medical therapy

  for adrenal cortical carcinoma, 2387–2388

  for genitourinary tuberculosis treatment, 1311*t*, 1315–1317, 1315*t*–1316*t*

Medical Therapy of Prostatic Symptoms (MTOPS) Trial, 3385–3386, 3387*f*–3388*f*, 3387*t*

Medication change, for ED, 1529

Medication optimization, in geriatric patient, 2915–2917, 2916*t*–2917*t*

Medication-related stones

  in renal calculi, 2032–2033

  surgical management of, 2077.e2–2077.e3

Medications

  benign prostatic hyperplasia and, 3324

  patient history of, 7–8

  transient urinary incontinence and, 2919.e1

Medullary cystic kidney disease (MCKD), 747*t*, 755–756, 756*f*, 756*b*

  clinical features of, 755–756

  evaluation of, 756, 756*f*

  genetics of, 755

  treatment of, 756

Medullary sex cord, 319*f*

Medullary sponge kidney (MSK), 771–772, 771*f*, 772*b*

  clinical features of, 771

  diagnosis of, 771

  histopathology of, 771

  prognosis of, 771–772

  renal calculi and, 2034–2035

  treatment of, 771–772

Megacalycosis, 738–739, 740*f*

Megacystis microcolon intestinal hypoperistalsis syndrome (MMIHS), 520–521

Megacystis-megaureter association, 510

Megaureter

- in children, 849–852, 852*b*
  - cutaneous ureterostomy for, 850–851, 850*f*
  - definition of, 849
  - definitive reconstruction for, 850–851, 850*f*
  - dilatation and stenting for, 852
  - etiology, occurrence, and presentation of, 849
  - excisional tapering for, 851–852, 851*f*
  - Kalicinski plication technique for, 851, 851*f*
  - outcomes with, 852
  - remodeling for, 837*f*–839*f*, 851
  - Starr plication technique for, 851, 851*f*
  - surgical indications for, 849–850
  - surgical management of, 850–852, 850*f*–851*f*
  - ureteral polyps with, 835–836
  - ureteral strictures with, 835
- ureteral calculi in, surgical management of, 2087
- ureterovesical junction obstruction, 374–375
  - recommendations for, 374–375

Meiosis, testis germ cells and, 1400–1401, 1401*t*

Melanocortin-receptor agonists, 1534

Melanocortins, in ED, 1494, 1495*t*

Melanoma, as neoplastic condition, 1300–1301

Melatonin, 1392

MELD score, in assessment of perioperative mortality, 121

Membrane potential, of smooth muscles, of bladder, 2473–2474, 2474*f*

Membranoproliferative glomerulonephritis (MPGN), 346

Membranous glomerulonephritis (MGN), with RPF, 1978

Membranous nephropathy (MN), 345

Membranous urethra, 1382, 1382*f*–1383*f*, 1807.e4*f*, 1807.e8

Memorial Sloan-Kettering Cancer Center (MSKCC) penile rehabilitation program, 3579

MEN, Multiple endocrine neoplasia

Menopause

- genito-pelvic pain-penetration disorder and, 1652
- pelvic organ prolapse and, 2591

Men's health, integrated, 1411–1427

- cardiovascular risk, and testosterone therapy, 1424–1425, 1425*b*
- health centers for, 1427
- mental health and opioid abuse in men, 1426–1427, 1427*b*
- metabolic syndrome and, 1417–1424, 1424*b*
- rationale for, 1411–1417, 1417*b*
  - gender longevity gap, 1411, 1412*t*–1415*t*, 1415*f*
  - global men's health movement, 1417
  - health and wellness gap by gender, 1411, 1415*t*
  - poorer health of men, explanation of, 1411–1416
  - targets and effective interventions, 1416–1417

Mental illness, in men, 1426

Mepartricin, for chronic scrotal pain syndrome, 1216

Meperidine (Demerol), urethral function effects of, 1902

Mesenchymal condensation, 3275–3276

Mesenchymal-epithelial conversion, 338

Mesenchymal tumors, of prostate, 3512

Mesenteric blood flow, pneumoperitoneum effects on, 222

Mesh complications, 2877–2888, 2878*b*

- among three slings, 2880–2887
- apical, 2886–2887
- exposure, treatment of, 2886–2887, 2886*f*
- male, 2887–2888, 2887*b*–2888*b*, 2888*f*
- materials for, 2877
- in midurethral sling, 2877
  - bladder, perforation of, 2868–2870, 2868*f*, 2869*t*, 2870*b*
  - contraction of, 2877

- exposure of, 2864–2866, 2864*f*, 2865*t*, 2866*b*, 2877, 2878*f*
- extrusion of, 2877
- perforation of, 2877, 2879*f*
- prominence of, 2877
- risk factors for, 2879–2880
- for stress urinary incontinence, 2879
- urethra, perforation of, 2866–2868, 2867*t*, 2870*b*

prolapse, treatment of, 2885

and properties, 2877–2878

surgical removal, 2885–2886, 2886*b*

surrounding, 2877

transvaginal (anterior and posterior wall), 2883–2885

Mesoderm, 305

Mesodermal origins, retroperitoneal tumors and, 2229

Mesonephric duct, 324*f*

degenerating, 319*f*

ureteral development from, 1877

Mesonephric tubules, 319*f*, 324*f*

Mesonephros, 324*f*, 334–335, 334*f*

Mesotheliomas, of testicular adnexa, 1709

Mesovarium, 2437–2438

MESTs, Mixed epithelial and stromal tumors

MET, Medical expulsive therapy

MET gene, systemic therapy targeting, 2343, 2344*f*

MET signaling, in castration-resistant prostate cancer, 3701

Metabolic changes, with aging, 2906

Metabolic syndrome (MetS)

benign prostatic hyperplasia and, 3324, 3325*t*

bladder cancer, 1421

definition of, 1417–1418, 1417*f*, 1418*t*

and ED, 1510–1511

hormonal therapy and, 3681

  - hyperoxaluria and, 2059–2060
  - novel strategy for, 1422
    - diet and exercise, 1422
    - metformin, 1422
    - statins, 1422
    - testosterone therapy, 1422
  - physiology of, 1418–1420, 1419*f*
    - abdominal obesity, 1418–1419
    - dietary factors, 1420
    - dyslipidemia, 1419
    - endothelial dysfunction, 1420
    - genetics, 1420
    - glucocorticoid and stress-response mediators, 1420
    - hypercoagulable state, 1420
    - hypertension, 1419–1420
    - insulin resistance, 1419
    - obstructive sleep apnea, 1420
  - prevalence and predictors of, 1418
  - renal calculi and, 2008
  - sleep duration and, 2665–2666
  - urologic disorders and, 1420–1422
    - bladder cancer, 1421
    - erectile dysfunction, 1422
    - low testosterone and erectile dysfunction, 1422
    - lower urinary tract symptoms, 1421
    - overactive bladder, 1421
    - prostate cancer, 1421–1422
    - renal insufficiency, 1420
    - renal stones, 1420–1421
    - tumor, 1421

Metabolomics, for prostate cancer biomarkers, 3479

Metanephric adenofibroma, in pediatric patients, 1109

Metanephric adenoma, of kidney, 2128–2129, 2129*f*, 2129*b*

Metanephric mesenchyme, ureteric bud outgrowth, 336–338, 337*f*

Metanephrine testing, for pheochromocytoma, 2377, 2377*f*

Metanephros, 335–336, 335*f*

Metaplastic lesion, of upper tract urothelium, 2188

Metastasectomy, in advanced RCC, 2328, 2328*b*

Metastasis
- adrenal disorder, 2388–2389, 2389*f*, 2390*b*
- after renal tumor ablation, 2317
- MRI and, 53–54
- neuroblastoma with, 1089
- of penile cancer
  - primary tumor histology in prediction of, 1757–1759, 1758*t*
  - prognostic significance of, 1753, 1754*t*–1755*t*
  - risk-based management for, 1762–1765, 1763*f*–1764*f*
- from prostate, castration-resistant, 3689–3690
- renal, 2181*t*, 2183
- testicular, 1124, 1709

Metastatic bladder cancer
- chemotherapy for, 3127*t*
- FDA-approved agents and future directions, 3130
- immune checkpoint inhibitor therapy, 3129–3130
  - first-line, 3130
  - second-line, 3130
- management of, 3112–3132, 3131*b*
- randomized trials in, 3127–3128, 3127*t*
- second-line chemotherapy for, 3128, 3128*t*
  - multiagent, 3129
  - single agent, 3128–3129, 3129*t*
- targeted therapy for, 3130–3131

Metastatic disease, treatment of, 2222–2224, 2223*f*

Metastatic potential, of UTUC, 2193–2194

Metastatic prostate cancer, castration-sensitive, phase III clinical trials for, 3678*t*

Metastatic RCC, 2177
- treatment of, 2325–2328
  - advanced, immunologic approaches, 2329–2332, 2329*t*–2331*t*, 2332*f*
  - chemotherapy, 2341–2342
  - debulking or cytoreductive nephrectomy, 2325–2328, 2326*f*–2327*f*, 2327*t*, 2328*b*
  - hormonal therapy, 2342–2343
  - palliative surgery, 2328, 2328*b*
  - prognostic factors and, 2324–2325, 2325*f*, 2325*t*
  - resection of metastases, 2328, 2328*b*
  - systemic therapy for non-clear cell variants, 2343–2344, 2344*f*

targeted molecular agents in, 2324, 2333–2341, 2333*t*–2335*t*, 2336*f*, 2337*t*

Metastatic restaging, in UTUC, 2225

Metformin, 449

and gadolinium, contrast media and, 34

and iodinated contrast, contrast media and, 33–34

for metabolic syndrome, 1422

for prostate cancer, 3545

in prostate cancer prevention, 3475

Methacholine (Mecholyl), ureteral response to, 1887

Methenamine, for UTIs, 1165–1166, 1165*t*

Methotrexate

for BPS/IC oral therapy, 1241*t*, 1243

for penile cancer, 1770

Methoxamine, for stress urinary incontinence in women, 2714

α-Methylacyl coenzyme A racemase *(AMACR)* gene, as prostate cancer biomarker, 3487

Methylene blue

for pelvic floor disorder testing, 2533

toxicity of, 1994

ureteral response to, 1886

Methylprednisolone sodium succinate, for contrast media, 32

Methysergide (Sansert), with RPF, 1978

Meticulous padding, 164–165, 165*f*

Metoclopramide, to facilitate bladder emptying, 2718

Metoidioplasty, 3068–3069

Metronidazole, prophylaxis with, for uncomplicated urologic procedures, 1194*t*–1196*t*

MetS, Metabolic syndrome

Meyers scale, 473–474, 474*f*

MGN, Membranous glomerulonephritis

MGP, Matrix GLA protein

MHCs, Myosin heavy chains

MI, Mechanical index

Mic-Key button, for bladder emptying, 711

Microbiology, TB, 1307

Microbiome, in GU cancers, 1368–1369, 1369*b*

Microductal aplasia, 1449–1450

Microductal obstruction, 1447, 1447*f*

Microfibrillar collagen (Avitene), 147

Microhematuria, 401

Microlithiasis, testicular, in pediatric patients, 1124–1125

Micromotions, 2642

Micronutrients, for prostate cancer, 3544

Micropapillary urothelial carcinoma (MPUC), 3088

Micropenis, 872*t*, 879–880, 880*f*, 880.e1*b*, 881*b*

Microphthalmia-associated transcription factor-associated cancer syndrome, 2145

Microporous polysaccharide spheres (Arista), 147

MicroRNA (miRNA), as prostate cancer biomarker, 3487

Microsatellite instability, in UTUC, 2197

Microscopic hematuria, 247–250, 250*b*, 252*b*, 479

- American Urologic Association (AUA) guideline panel define, 247
- causes of, 247, 248*b*, 249*t*
- criteria for diagnosis of, 247, 248*t*
- cystoscopy in diagnostic evaluation of, 250–251
- guideline-based evaluation of, 250–252, 251*f*
- natural history, in patients with negative evaluation, 252
- requirement for, 247
- screening for, 250

selection of patient, for evaluation of, 247–250, 248*t*

symptomatic, 252

Microsurgical denervation of the spermatic cord (MDSC), 1853–1855, 1854*f*–1855*f*

Microsurgical epididymal sperm aspiration, in sperm retrieval, 1473–1474, 1473*f*–1474*f*

Microwave ablation (MWA), for renal tumors, 2322

Micturating cystourethrogram, 415–416

Micturition

- brainstem modulatory mechanisms of, 2493–2494, 2495*f*
- cerebral control of, 2496
- charts, 3344

  - among three slings, 2880–2887
  - contraction of, 2877
  - exposure of, 2877, 2878*f*
  - extrusion of, 2877
  - perforation of, 2877, 2879*f*
  - prominence of, 2877
  - risk factors for, 2879–2880
  - for stress urinary incontinence, 2879
- operative procedures for, 2851–2863
  - anesthesia for, 2851–2854
  - patient counseling for, 2851
  - positioning for, 2851–2854
  - preparation for, 2851–2854
- outcomes of
  - for elderly women, 2862–2863, 2863*b*
  - for intrinsic sphincteric deficiency, 2859–2860
  - for mixed urinary incontinence, 2858–2859
  - for obese patients, 2863, 2863*b*
  - for pelvic organ prolapse, 2861–2862
  - for predominantly SUI, 2854
  - for recurrent SUI, 2860–2861, 2861*b*
- retropubic

- anatomy of, 2850
- complications of, 2863–2866
- outcomes for, 2854–2856, 2855*t*
- removal of, 2870
- surgical approach to, 2851–2853, 2852*f*–2853*f*

retropubic, complications of, 2880

single-incision
- anatomy of, 2851
- complications of, 2863–2866, 2879
- outcomes for, 2857–2858
- surgical approach to, 2854, 2855*f*

for stress urinary incontinence, 2879

transobturator
- anatomy of, 2850–2851
- complications of, 2863–2866
- inside-out, surgical approach for, 2853–2854, 2854*f*
- outcomes for, 2856–2857, 2857*t*
- outside-in, surgical approach for, 2853

Mild androgen insensitivity syndrome, 1014

Milnacipran hydrochloride, to facilitate bladder filling and urine storage, 2702

Mindfulness, for female orgasmic disorder, 1647

Mineral metabolism, 2017*b*

Mineralocorticoids, in adrenal histology, 2356, 2357*t*

Mini balloon button, for bladder emptying, 711

Mini Mental State Examination (MMSE), 2910

Mini-Cog, 2910, 2911*f*

Minimally invasive and endoscopic management of benign prostatic hyperplasia, 3403–3448

defining outcomes for, 3405–3407
- comparing to other treatments, 3407, 3408*t*
- response rates, 3405–3407
- secondary procedures, 3407

epidemiology of, 3403–3404, 3404*b*

failed, failing, and future directions for, 3443–3447
- aquablation (aquabeam), 3444–3445, 3445*f*
- prostate embolization, 3445–3446
- prostate stents, 3443–3444

    - prostatic injections, 3446–3447
    - Temporary Implantable Nitinol Device, 3444
  - increasing age and, 3404
  - laser treatments, 3435–3438
    - safety for, 3435–3436
  - marketshare, 3403–3404, 3404*b*
  - non-laser options for, 3409–3443, 3422*b*, 3435*b*
  - presurgical factors for, 3407–3409, 3409*b*
    - antibiotic coverage for, 3409
    - histologic specimen for, 3409
    - matching treatment with patient, 3409
    - treatment indications, 3407–3409
  - workup for, 3404–3405, 3405*f*–3406*f*
- Minimally invasive ileal ureteral substitution, for ureteral stricture disease, 1973–1975, 1974*f*
- Minimally invasive pelvic lymph node dissection, 3584–3586
  - complications of, 3585–3586, 3586*b*
  - future of, 3586
  - indications for, 3584
  - surgical technique of, 3584–3585, 3585*f*
- Minimally invasive surgery (MIS)
  - access, 463–465, 465*b*
    - comparative effectiveness of, 465
    - open, 464, 464*f*
    - Veress needle, 463, 464*f*
    - visual obturator, 464–465
  - additional benefit of, 459
  - advantages and disadvantages of, 458–459, 459*f*, 459*t*, 460*b*
  - approach to, 465, 465*b*
    - retroperitoneal, 465
    - transperitoneal, 465
    - vesicoscopic, 465
  - assessment, 470
  - complications of, 468–469, 469*b*
    - incisional hernia, 468–469, 469*f*
    - pulmonary air embolus, 469
    - vascular injury, 468, 469*f*
    - visceral injury, 468

cost of, 460
drawbacks of, 460
learning curves, 472
length-of-stay benefits for selected, 458–459, 459*t*
patient selection for, 462–463, 463*b*
pediatric urologic procedures, 462*t*
simulation training and evaluation of, 469–472, 470*f*–471*f*, 472*b*
skills acquisition, stages of, 470*t*
training, 470
in urologic practice, 2308
warm-up, 471–472

Minimally invasive urinary diversion, 3258–3273
- anatomic considerations in
  - men, 3260–3261, 3260*f*
  - women, 3261
- complications of, 3270, 3271*t*
- Florin: Florence robotic intracorporeal neobladder, 3267
  - configuration and setup, 3267, 3267*f*
  - uretero-neobladder anastomosis, 3267
- functional outcomes with, 3272–3273
- future direction for, 3273
- hospital stay for, 3259
- ileal conduit, 3261–3262
  - bowel restoration, 3262
  - bowel segment isolation, 3262
  - bowel selection for, 3261
  - left ureter transfer for, 3261
  - marionette stitch, 3261–3262, 3261*f*
  - pre-stoma preparation, 3262, 3262*b*
  - ureteroileal anastomosis, 3262
- intracorporeal *versus* extracorporeal, 3273
- learning curve for, 3270
- modified Studer neobladder: Karolinska Institute Technique, 3263*t*, 3264–3265
  - bowel detubularization, 3264
  - closure of neobladder, 3265
  - configuration and setup, 3264, 3264*f*
  - neobladder creation, 3264
  - neobladder-urethral anastomosis, 3264
  - uretero-neobladder anastomosis, 3264

- modified Studer neobladder: The USC Institute of Urology Technique, 3265
    - configuration and setup, 3265, 3265*f*
    - neobladder-urethral anastomosis and cross-folding of pouch, 3265
    - rotation of pouch, 3265
    - uretero-neobladder anastomosis, 3265
- modified “W” Hautmann neobladder: The Roswell Park Comprehensive Cancer Center Technique, 3267–3269
    - configuration and setup, 3267–3268, 3268*f*
    - neobladder creation, 3268
    - uretero-neobladder anastomosis, 3268–3269
- modified Y neobladder: The Clinique Saint-Augustin Technique, 3266
    - configuration and setup, 3266, 3266*f*
    - neobladder creation, 3266
    - uretero-neobladder anastomosis, 3266
- operative time for, 3270
- outcomes with, 3270
- Padua neobladder, 3266–3267
    - configuration and setup, 3266–3267, 3267*f*
    - uretero-neobladder anastomosis, 3267
- patient position for, 3259–3260, 3259*f*, 3260*b*
- patient selection for, 3258
- port placement for, 3259–3260, 3259*f*, 3260*b*
- postoperative care for, 3269–3270
- preoperative care for, 3259, 3259*b*
- pyramid neobladder: The University College London Hospital technique, 3265–3266
    - configuration and setup, 3265, 3266*f*
    - formation of, 3265–3266
    - uretero-neobladder anastomosis, 3266
- surgeon choice in, 3258–3259

Mi-Prostate Score (MiPS), 3486

MiPS, Mi-Prostate Score

Mirabegron, 2500, 2544
- adverse effects of, 2700
- for benign prostatic hyperplasia, 3381–3393
- for diminished bladder, 2674, 2675*t*–2677*t*
- efficacy of, 2699–2700
- to facilitate bladder filling and urine storage, 2682*t*, 2699–2700
    - with antimuscarinics, 2706

  - indication, efficacy, and safety profile of, 3381–3382
  - for OAB, 2647
  - pharmacokinetics of, 2699
  - tolerability of, 2700
  - for urinary incontinence, in geriatric patients, 2920.e4

MIS, Minimally invasive surgery

Mismatch repair (MMR), 1351.e1, 1351.e1*f*

Misoprostol, for BPS/IC oral therapy, 1241*t*, 1243

Mitchell repair, for classic bladder exstrophy, 544, 544*f*
  - continence outcomes with, 560
  - technical aspects of, 550, 550*f*

Mitomycin C (MMC), for non-muscle-invasive bladder cancer, 3104–3105

Mitosis
  - deregulation of, in GU cancers, 1347.e2
  - in UTUC, 2197–2198

Mitotic arrest, deregulation of, 1347.e3

Mitoxantrone, 3690, 3693*f*

Mitrofanoff principle, for continent urinary diversions, 707–709

MIV, Minverted V glansplasty

Mixed epithelial and stromal tumors (MESTs), of kidney, 2130, 2130*f*, 2130*b*

Mixed fiber mesh, for anterior compartment repair, 2781*t*–2782*t*

Mixed gonadal dysgenesis, 998*t*, 1002–1004, 1003*f*, 1003*b*, 1004*t*

Mixed mesenchymal and epithelial tumors, renal, 2129–2130, 2129*f*

Mixed urinary incontinence (MUI)
  - definition of, 2539, 2581
  - midurethral sling for, outcomes of, 2858–2859
  - overactive bladder and, 2637
  - patient history of, 5
  - pubovaginal sling for, outcomes of, 2844–2845
  - treatment of, 2547

MK2206, 3700

MLCs, Myosin light chains

M-line measurement, 2441–2442, 2442*f*

MMC, Mitomycin C

MMIHS, Megacystis microcolon intestinal hypoperistalsis syndrome

MMR, Mismatch repair

MMSE, Mini Mental State Examination

MN, Membranous nephropathy

Modafinil, for PE, 1572.e2–1572.e3

Modern staged reconstruction, of cloacal exstrophy, 578, 578*t*

Modern staged repair of exstrophy (MRSE), 545

- bladder, posterior urethral, and abdominal wall closure for, 545–548, 546*f*–548*f*
- combined bladder closure and epispadias repair, 548
- management after, 548–549, 549*b*

Modified Cantwell-Ransley repair, for classic bladder exstrophy, 551–552, 552*f*–553*f*

Modified cardiac risk index, 120*t*

Modified complete ILND, for penile cancer, 1761

Modified inguinal lymph node dissection, for penile cancer, 1794

Modified supine positioning, 467*f*

Modified Young-Dees-Leadbetter bladder neck reconstruction, 555*f*–556*f*

Modulators, within brainstem networks, 2495–2496

Mohs micrographic surgery, for penile cancer, 1752

Mole, 1304, 1305*f*

Molecular genetics of GU cancers, 1346–1369, 1346.e1–1346.e4

- apoptosis, 1365–1367, 1367*b*
  - extrinsic pathway of, 1366.e1*f*–1366.e2*f*, 1366.e2
  - intrinsic pathway of, 1366.e1, 1366.e1*f*
- basic concepts for

    chromosomes and gene structure, 1346.e4
    DNA, 1346.e1–1346.e4, 1346.e2*f*
    protein synthesis, 1346.e3–1346.e4, 1346.e3*f*–1346.e4*f*
    transcription, 1346.e3, 1346.e3*f*
cell cycle deregulation, 1347–1348, 1349*b*
    CDKIs, 1347.e1, 1347.e1*f*
    cell cycle entry, 1347.e1
    cell cycle progression through S phase, 1347.e2
    cyclin-dependent kinases and cyclins, 1347.e1, 1347.e1*f*
    G_1/S checkpoint, 1347.e2
    G2M checkpoint, 1347.e2–1347.e3
    mitosis, 1347.e2
    mitotic arrest and spindle assembly checkpoint, 1347.e3
    RB1, 1347.e1, 1347.e1*f*
    S phase arrest, 1347.e2
    TP53, 1347.e2, 1347.e2*f*, 1348
checkpoint inhibition, 1367–1368, 1368*b*
DNA damage and repair, 1350–1351, 1351*b*
    DSB repair, 1351.e1*f*–1351.e2*f*, 1351.e2
    mechanisms, 1351.e1, 1351.e1*f*
DNA methylation, 1348–1350, 1350*b*
genomic alterations, 1351–1362, 1362*b*
    in bladder cancer, 1358–1360
    bladder RMS, 1111–1113
    CNAs, 1354, 1354*t*–1355*t*
    gross chromosomal abnormalities, 1351–1352, 1352*b*
    in prostate cancer, 1352–1353, 1354*t*, 1355*f*
    in renal cancer, 1353, 1354*t*, 1358
    in testicular cancer, 1121, 1353, 1361–1362
    in Wilms tumor, 1096–1099, 1097*t*, 1354*t*
microbiome, 1368–1369, 1369*b*
oncogenes, 1346–1347, 1347*b*
stem cells, 1367, 1368*b*
telomerase, 1362–1365, 1363*f*, 1365*b*
    chromosome stabilizing activity of, 1364
    as potential diagnostic marker, 1364
    therapies based on, 1365
telomeres, 1362–1365, 1365*b*
    cancers and premalignant lesions with short, 1363–1364
    chromosomal instability and, 1362
    prostate cancer prognosis using, 1364–1365
    as tumor suppressive mechanism, 1363, 1363*f*

    - terminology for, 1346.e1*b*–1346.e2*b*
    - tumor suppressor genes, 1346–1347, 1347*f*, 1347*b*
- Molecular imaging, 91
- Molecular oxygen, penile erection and, 1500
- *Molluscum contagiosum*, 1261, 1261*f*
- Monfort technique, 595, 596*f*–597*f*
- Monopolar electrocautery, 466
- Monopolar electrosurgery
    - argon beam coagulator, 215.e1
    - devices for, 237
        - in laparoscopic and robotic surgery, 214
    - generator settings for, 235–236
    - physics of, 235, 236*f*
    - safety of, 236–237
- Monopolar thermal energy, 468
- Monopolar transurethral resection of the prostate (M-TURP), 3409–3418
    - in anticoagulated patient, 3416
    - complications of, 3416–3418
        - intraoperative, 3416–3417
        - perioperative, 3416–3417
        - postoperative, 3417–3418
    - conclusion for, 3418
    - outcomes with, 3416
    - technique for, 3410–3416
        - intraoperative, 3410–3415, 3411*f*–3414*f*, 3414*f*–3415*f*
        - postoperative, 3415–3416
        - preoperative, 3410
- Monosymptomatic enuresis (MSE), 660
- Mons pubis, 1627.e1, 2435, 2436*f*–2437*f*
- Montelukast, for BPS/IC oral therapy, 1241*t*, 1242
- Monti procedure, for ureteral injury, upper, 1998
- Morbid obesity, in urologic surgery, 122

Morcellation instrumentation, for laparoscopic and robotic surgery, 218

Morphine, urethral function effects of, 1902

Mortality
  after RPLND, 1731
  with benign prostatic hyperplasia, 3335
  definition of, 102
  early, nocturia and, 2664–2666
  in locally advanced prostate cancer, 3644, 3645*f*
  prostate cancer, rates of, 3457, 3458*f*
    global, 3458–3459
    screening effect of, 3459–3460
  rate, 102

Motility, sperm, 1404–1405, 1405*f*

Motor nerve innervation, in detrusor muscle, 2465, 2465*f*, 2480, 2480*f*

Motor paralytic bladder, 2522

MPGN, Membranoproliferative glomerulonephritis

MPUC, Micropapillary urothelial carcinoma

MRA, Magnetic resonance angiography

MRI, Magnetic resonance imaging

MRKH, Mayer-Rokitansky-Küster-Hauser syndrome

MRSE, Modern staged repair of exstrophy

MRSI, Magnetic resonance spectroscopic imaging

MRU, Magnetic resonance urography

MS, Multiple sclerosis

MSA, Multiple system atrophy

MSE, Monosymptomatic enuresis

MSK, Medullary sponge kidney

^{99}mTc hexamethylpropyleneamine oxine (^{99}mTc-HMPAO), 96

mTOR, Mammalian target of rapamycin

M-TURP, Monopolar transurethral resection of the prostate

Mucinous cystadenoma, retroperitoneal tumors and, 2237

Mucosal glands, 315*f*

Mucosal plexus, 2463

MUCP, Maximum urethral closure pressure

Mucus, after augmentation cystoplasty, 698

MUI, Mixed urinary incontinence

Müllerian Aplasia, 980–981, 981*f*

Müllerian duct, 324*f*

Müllerian-inhibiting substance (MIS), 317–318, 1392, 1392*f*

Müllerian tubercle, 324, 776

Multichannel UDS, 2536, 2565*f*

Multicystic dysplastic kidney (MCDK), 339–340, 349, 350*b*, 377–378, 378*f*, 401, 405, 762–765, 762*f*, 765*b*

- clinical features of, 762
- duplex anomaly, recommendation of, 379, 381*f*
- duplication anomalies/ureterocele/ectopic ureter, 378–379, 379*f*–380*f*
- etiology of, 762
- evaluation of, 763, 763*f*–764*f*
- histopathology of, 762–763, 763*f*
- prognosis of, 763–765
- recommendations for, 378
- treatment of, 763–765

Multidetector computed tomography urography (CTU), for urinary tract obstruction, 779–780

Multidisciplinary approach, to pelvic pain study, 1209–1210

Multidisciplinary team, in transitional urology, 1045

Multidrug-resistant tuberculosis, 1318

Multimodal physical therapy, for genito-pelvic pain-penetration disorder, 1653

Multiparametric magnetic resonance imaging, 66, 66*f*–67*f*, 66*t*
  of prostate, 3502–3504, 3502*t*–3503*t*, 3502*b*, 3504*f*
  for prostate cancer, 3621–3622
Multiparametric ultrasonography, 77*f*
  prostate, 3502
  for prostate cancer, 3622
Multiple endocrine neoplasia (MEN), genomic alterations in, 1354*t*–1355*t*
Multiple malformation syndromes with renal cysts, 747*t*, 757–761
  tuberous sclerosis complex, 757–759
  von Hippel-Landau disease, 759–761
Multiple sclerosis (MS)
  cause of, 2607
  lower urinary tract dysfunction and, 2607–2608
  overview of, 2607
  treatment for, 2608
Multiple system atrophy (MSA), lower urinary tract dysfunction with, 2606–2607, 2607*b*
MUP, Maximum urethral pressure
MUPP, Micturitional urethral pressure profile
MUS, Midurethral sling
Muscarinic receptor antagonists, for benign prostatic hyperplasia, 3379–3381
  efficacy of, 3379–3381, 3380*t*
  rationale and indication for, 3379, 3379*t*
  summary for, 3381
  tolerability and safety profile of, 3381
Muscarinic receptors
  in bladder function, 2470
    contraction, 2679–2681
  distribution of, 2680*t*
  pharmacology of, 2497–2500, 2499*t*, 2500*b*
    for detrusor underactivity, 2661
    selectivity of, 2499

Muscle-invasive bladder cancer
  adjuvant chemoradiation for, 3122
  adjuvant chemotherapy for, 3120–3125
    randomized trials of, 3121–3123, 3121*t*
  bladder preservation with, 3122–3123
    partial cystectomy, 3124–3125
    radiation monotherapy, 3124
    radical transurethral resection, 3124
    single modality treatment for, 3124–3125
    trimodal therapy for, 3123, 3123*t*
    trimodality therapy for, 3123–3124
  clinical presentation of, 3112–3114
  clinical staging for, 3112–3113, 3113*t*
  diagnosis of, 3112–3114
  grossly positive nodes and, 3117
  histology of, 3112
  management of, 3112–3132, 3131*b*
  natural history of, 3112
  neoadjuvant chemotherapy for, 3119–3120, 3120*t*
  pathologic staging for, 3113–3114, 3114*t*
  prognostic nomograms for, 3125–3127, 3126*f*
  radical cystectomy and pelvic lymph node dissection for, 3114–3119
Muscles
  of abdominal wall, lower, 2444–2448, 2447*f*–2448*f*
  of pelvic floor
    female, 2430–2432, 2432*f*
    male, 2449, 2449*f*
  in prune-belly syndrome, 587, 600
Musculocutaneous artery, 136*f*
Mutation, androgen receptor and, 3685–3686
Mutations (SPOP, FOXA1, IDH1), tumors defined by, 3470–3472, 3470*f*
MVV, Maximum voided volume
MWA, Microwave ablation
Myasthenia gravis
  contrast media and, 32

lower urinary tract dysfunction and, 2630

Mycobacterium tuberculosis, 1133

Mycophenolate mofetil (CellCept), for BPS/IC oral therapy, 1243

Mycoplasma genitalium, 1253–1254

Myelodysplasia

early intervention in, 628

renal dysfunction in, 629

sexuality and, 629–630

Myelolipoma

as benign lesions, 2392, 2392*f*, 2392*b*

MRI and, 52–53, 53*f*–56*f*, 58*f*

Myelomeningocele

closure, prenatal counseling for prenatal surgery for, 362

lower urinary tract dysfunction with, 2617

prenatal closure of, 625

presentation of, 625*f*

urologic surgery and, 288–290

Myofibroblasts, 2470, 2470*f*

and PD, 1605

Myogenic hypothesis, 2642

Myoplasty

for bladder emptying, 2903

stimulated, 2903

Myosin, in thick filaments, 2471, 2471*f*

Myosin heavy chains (MHCs), 2471, 2471*f*

Myosin light chains (MLCs), 2471

Myotonic dystrophy, lower urinary tract dysfunction and, 2631

N

NAATs, Nucleic acid amplification tests

Naftopidil
  for benign prostatic hyperplasia, 3365–3367, 3367*t*
  to facilitate bladder filling and urine storage, 2682*t*
  for ureteral stone passage, 1900

Naloxone, to facilitate bladder emptying, 2719

Narcotic considerations, patient history of, 2–3

Narrow band imaging (NBI), for non-muscle invasive bladder cancer, 3097–3098

NASA TLX, National Aeronautics and Space Administration Task Load Index assessment

National Aeronautics and Space Administration Task Load Index assessment (NASA TLX), 471

National Institutes for Clinical Excellence Guidelines, 507

Natriuretic peptides, in ED, 1498

Natural orifice transluminal endoscopic surgery (NOTES), 2421
  instrumentation for, 218
  for kidney surgery, 2284–2285, 2285*f*, 2286*t*

NBCi, Nocturnal bladder capacity index

NBI, Narrow band imaging

NCCT, Noncontrast computed tomography

NDO, Neurogenic detrusor overactivity, Nocturnal detrusor overactivity

Nd:YAG, Neodymium:yttrium-aluminum-garnet

Near-infrared spectroscopy (NIRS), for benign prostatic hyperplasia, 3349

Necrosis
  PC-RPLND findings of, survival outcomes associated with, 1726
  penile, implant for, 1595–1596, 1595*f*

Needle biopsy
  for prostate adenocarcinoma, 3509–3510, 3510*b*
  for prostate cancer, 3519–3520

Needle drivers, for laparoscopic and robotic surgery, 215, 215.e3*f*

Needle suspension repair, retropubic suspension surgery *versus*, 2771

Negative feedback, in HPG axis, 1390, 1391*f*

Neoadjuvant androgen deprivation

- with radiation therapy, for locally advanced prostate cancer, 3652–3653, 3654*b*
- with radical prostatectomy, for locally advanced prostate cancer, 3648–3649, 3648*t*–3649*t*

Neoadjuvant chemotherapy, for muscle-invasive bladder cancer, 3119–3120, 3120*t*

Neoadjuvant chemotherapy-hormonal therapy, with radical prostatectomy, for locally advanced prostate cancer, 3649–3650, 3650*t*

Neobladder-urethral anastomosis

- maneuvers facilitating, 3268–3269
- for minimally invasive urinary diversion, 3264

Neodymium:yttrium-aluminum-garnet (Nd:YAG), 239

Neonatal urologic emergencies, 382–383

Neonates

- hydronephrosis diagnosis in, 1943
- with UPJO, 1943

Neoplasia, of bladder, 1360–1361

Neoplastic conditions, of cutaneous diseases of external genitalia

- basal cell carcinoma, 1297–1298, 1300*f*
- bowenoid papulosis, 1296, 1298*f*
- cutaneous T-cell lymphoma, 1302, 1302*f*
- extramammary Paget disease, 1301–1302, 1301*f*
- Kaposi sarcoma, 1298–1299, 1300*f*
- melanoma, 1300–1301
- pseudoepitheliomatous, keratotic, and micaceous balanitis, 1299–1300, 1300*f*
- squamous cell carcinoma, 1296, 1299*f*
- squamous cell carcinoma in situ, 1296, 1298*f*
- verrucous carcinoma, 1296–1297, 1299*f*

Neostigmine, ureteral response to, 1887–1888

Nephrectomy, 444
  for genitourinary tuberculosis treatment, 1317
  history of, 2133
  for metastatic RCC, 2325–2328, 2326*f*–2327*f*, 2327*t*, 2328*b*
  open, technique of, 2254, 2254.e1*f*
  renal bleeding and, 1988–1989
  in renal transplantation, 1058
  for renal trauma
    partial, 1989–1990, 1989*f*
    total, 1991
  for retroperitoneal tumors, 2243
  RPLND with, 1718, 1718*t*
  segmental, for large polar tumors, 2263–2264, 2263.e1*f*–2263.e2*f*, 2264.e1*f*, 2265*f*
  for ureteral anomalies
    laparoscopic partial, 811–813, 814*f*
    open partial, 811, 812*f*–814*f*
    upper pole partial, 811–813, 812*f*, 814*b*
  for ureteral injuries, upper, 1998
  for ureteropelvic junction obstruction, 1946–1947
Nephric ducts, formation of, 336
Nephroblastomatosis, 1101, 1101*f*
Nephrocalcin
  in crystal formation, 2014
  in crystal matrix, 2015
Nephrogenic adenoma, 526
  of bladder, 3082
    in pediatric patients, 1119
Nephrogenic rests, 1100–1101, 1101*f*
Nephrogenic systemic fibrosis (NSF), 773
  contrast media and, 34–35

Nephrolithiasis, 400, 1939, Urinary lithiasis
  child with, 854–856, 855*f*–856*f*
  HIV and, 1266
  treatment of, 1939
Nephrolithotomy
  percutaneous, 243.e1, 244.e3
    for bladder stones, 244.e3–244.e4
    ShockPulse-SE, 245–246
  for ureteropelvic junction obstruction, percutaneous antegrade endopyelotomy simultaneous with, 1949
Nephrolysis, laparoscopic, 2294, 2294*f*
Nephron, 1866–1868, 1867*f*
  anatomy, 1906, 1906*f*–1907*f*, 1907*b*
  hydrogen ion transport in, urinary tract obstruction and, 793
  sodium transport in, urinary tract obstruction and, 793
Nephronophthisis, 350
Nephron-sparing surgery, for RCC, 2173–2174, 2174*f*
Nephropathy, aristolochic acid, 2196
Nephropexy, laparoscopic, 2292–2294, 2293*f*
  procedure for, 2293*f*
  results of, 2293–2294
Nephropleural fistula, 180
Nephrostomy tract, establishment of, in antegrade nephroureteroscopic, for UTUC, 2215–2216, 2215*f*
Nephrostomy tube, for pediatric genitourinary trauma, 1072
Nephrotic syndrome, in children, 344–345
Nephroureteral stent, 173, 174*f*, 176*b*
Nephroureterectomy
  for posterior urethral valves, 615
  radical, 2199–2202
    distal ureter and bladder cuff management, 2200

- indications of, 2199
- laparoscopic, 2202–2205
- open, 2199–2200, 2200*f*
- total laparoscopic technique in, 2202, 2203*f*
- traditional open distal ureterectomy in, 2200–2201, 2200*f*–2201*f*
- transurethral resection of ureteral orifice, 2201–2202, 2202*f*
- transvesical ligation and detachment technique in, 2201, 2201*f*

robot-assisted, 2205, 2205*f*

transperitoneal, 2203–2204, 2203*f*–2204*f*

NER, Nucleotide excision repair

Nerve growth factor (NGF)
- in bladder outlet obstruction, 2506
- in bladder pain syndrome and interstitial cystitis, 2508
- in detrusor overactivity, 2505
- in overactive bladder, 2504

Nerve injury, during laparoscopic and robotic surgery, 230

Nerve sheath tumors, retroperitoneal tumors and, 2235–2236, 2236*f*

Nerves, adrenal, 2345, 2350*f*

Nerve-sparing RPLND, 2241–2242, 2242*f*

Nervous system
- of lower urinary tract, peripheral nervous system, 2480–2497, 2480*f*
- of retroperitoneum, 1674–1679
  - autonomic nervous system, 1674–1675, 1676*f*–1677*f*
  - somatic nervous system, 1675–1679, 1675.e1*f*, 1677*f*–1678*f*, 1679*t*
- in ureteral function
  - parasympathetic, 1887–1888
  - purinergic, 1889–1890
  - sensory innervation and peptidergic agents, 1889
  - sympathetic, 1888–1889

Nested variant, of urothelial cancer, 3088

Neural injury, in robotic prostatectomy, 3580

Neural tube defects (NTD), 624–631, 626*b*
- early intervention for, 628–629, 629*b*
- epidemiology of, 624
- findings with, 626–628

- pathogenesis of, 624, 626*t*
- perinatal concerns with, 625
- postnatal management of
  - congenital neurogenic bladder, 631, 631*f*, 632*t*
  - initial, 626
  - neurogenic bowel dysfunction, 631
- prenatal closure of, bladder function after, 625
- prevention of, 290
- risk factors for, 624
- upper urinary tract deterioration with, 626–628, 627*f*

Neurobiology, in BPS/IC etiology, 1232.e7–1232.e9, 1232.e9*b*

Neuroblastoma, 1087–1096, 1096*b*, 2388

- clinical presentation and pattern of spread of, 1088–1089, 1089*f*
- diagnosis of
  - imaging, 1089, 1089*f*–1090*f*
  - laboratory evaluation, 1089
  - screening, 1089–1090
  - staging, 1090–1091, 1090*t*–1091*t*
- epidemiology and genetics of, 1087
- pathology of, 1088, 1088*f*–1089*f*
- prognosis of, 1091–1092
  - biologic variables affecting, 1092
  - clinical variables affecting, 1091–1092
- in retroperitoneum, 2234
- spontaneous regression of, 1087–1088
- treatment of
  - biologic therapies, 1095–1096
  - chemotherapy, 1093*f*, 1095
  - radiotherapy, 1096
  - spinal cord decompression, 1096
  - surgery, 1092–1095, 1093*f*

Neuroendocrine cells, of prostate, 3278*f*, 3279

Neurofibroma, 1304, 1305*f*

- in retroperitoneum, 2235

Neurogenic acontractile detrusor, 2565

Neurogenic bladder

  - autonomous, 2522
  - with CNS tumors, 648
  - diminished bladder capacity and, 2671
  - reflex, 2522
  - renal transplantation and, 1057–1058
  - sensory, 2522
  - uninhibited, 2522

Neurogenic bladder dysfunction, 2964

Neurogenic bowel dysfunction, management of, with spina bifida, 631

Neurogenic detrusor overactivity (NDO), 2521
  - capsaicin for, 2709.e1
  - detrusor underactivity and, 2521
  - resiniferatoxin in, 2709.e1
  - urinary incontinence and, 2595

Neurogenic lower urinary tract dysfunction (NLUTD)
  - urodynamic studies, evidence-based review of, 2577–2578
  - videourodynamics for, 2569–2570

Neurogenic origins, retroperitoneal tumors and, 2234

Neuroimaging, in ED, 1526

Neurologic complications, after RPLND, 1731, 2244

Neurologic conditions, pelvic floor disorders and, 2527

Neurologic disease
  - detrusor underactivity and, 2657, 2657*b*
  - prostatitis and, 1210

Neurologic examination
  - for pelvic floor disorders, 2530
  - physical examination for, 12, 12*f*

Neuromodulation, Electrical stimulation
  - for bowel-bladder dysfunction, 658, 659*t*
  - for BPS/IC treatment, 1246–1247, 1247*b*
  - for chronic scrotal pain syndrome, 1221

- for lower urinary tract dysfunction, 2510–2512
    - to inhibit OAB, rationale for, 2511, 2511*f*
    - inhibitory and excitatory stimulation frequencies, 2511
    - onabotulinumtoxinA, 2512
    - pudendal nerve stimulation, 2511
    - somatic afferents activation, in foot, 2511–2512
    - for voiding, rationale for, 2510, 2510*f*
- for neuromuscular dysfunction of lower urinary tract, 637–638
- sacral, mechanism of action, 2510
- for urinary incontinence, in geriatric patients, 2920.e5

Neuromuscular complication, in urologic surgery, 261–262

Neuromuscular dysfunction of lower urinary tract, 624–651, 2600–2636, Voiding dysfunction

- acquired immunodeficiency syndrome and, 2625
- acute disseminated encephalomyelitis and, 2625–2626
- aging and, 2633
- amyloidosis, 2632
- amyotrophic lateral sclerosis and, 2624
- attention-deficit/hyperactivity disorder, 2633
- bashful bladder, 2628–2629
- benign joint hypermobility syndrome, 2633
- bladder neck dysfunction, 2627–2628
- bladder outlet obstruction in women, 2628
- in children
    - anorectal malformation, 644–645
    - causes of, 624, 625*t*
    - management principles for, 632–638, 632*t*–633*t*, 633*b*
    - medical management for, 633–634, 633*t*, 638*b*
    - neuromodulation for, 637–638
    - renal function assessment with, 629–631
    - surgical management of, 635–638, 638*b*
    - vesicoureteral reflux in, 638–639, 638*f*, 639*b*
- congenital adrenal hyperplasia, 2633
- corticobasal degeneration, 2631
- defunctionalized bladder, 2632–2633
- detrusor sphincter dyssynergia and, 2627
- distal to spinal cord, 2619–2624
    - childbirth, 2621

  - diabetes mellitus, 2622–2624, 2624*b*
  - disk disease, 2619–2620
  - Guillain-Barré syndrome, 2624
  - herpesvirus infection, 2621–2622
  - hysterectomy, 2621
  - radical pelvic surgery, 2620–2621
  - spinal stenosis, 2620
- dysfunctional voiding, 2627
- Ehlers-Danlos syndrome, 2631
- Fowler syndrome, 2629
- gastroparesis, 2630
- hereditary spastic paraplegia and, 2624–2625
- hyperthyroidism, 2630
- Isaacs syndrome, 2630
- Lyme disease and, 2624
- Machado-Joseph disease, 2632
- myasthenia gravis, 2630
- myotonic dystrophy, 2631
- neuroplasticity and, 2600–2602
- at or above brainstem, 2602–2607
  - brain tumor, 2604
  - brainstem stroke, 2603
  - cerebellar ataxia, 2604
  - cerebral palsy, 2604–2605
  - cerebrovascular disease, 2602–2603
  - dementia, 2603–2604
  - multiple system atrophy, 2606–2607, 2607*b*
  - normal-pressure hydrocephalus, 2604
  - Parkinson disease, 2605–2606
  - progressive supranuclear palsy, 2607
  - traumatic brain injury, 2604
- patterns of, 2600–2602, 2601*t*
- radiation, 2632
- reflex sympathetic dystrophy and, 2626
- sacrococcygeal teratoma, 2631
- schistosomal myelopathy and, 2626
- schizophrenia, 2630
- spinal cord involvement in, 2607–2619
  - acute transverse myelitis, 2617

        - autonomic dysreflexia, 2614–2615
        - bladder cancer and, 2616
        - cervical myelopathy, 2617
        - follow-up for, 2616–2617
        - multiple sclerosis, 2607–2608
        - neurologic and urodynamic correlation, 2612–2614
        - neurospinal dysraphism, 2617–2619
        - pernicious anemia, 2619
        - poliomyelitis, 2619
        - sacral injury, 2611–2612, 2613*f*, 2613*b*
        - spinal cord injury, 2609–2617, 2609*b*
        - spinal shock, 2610
        - subacute combined degeneration, 2619
        - suprasacral injury, 2610–2611, 2611*f*–2612*f*, 2612*b*
        - tabes dorsalis, 2619
        - urinary tract infection, 2615
        - vesicoureteral reflux, 2615
        - in women, 2615–2616
    - syringomyelia and, 2626
    - systemic lupus erythematosus and, 2626
    - systemic sclerosis, 2631
    - treatment of, 2634–2635, 2634*b*
    - tropical spastic paraparesis and, 2625
    - tuberculosis and, 2626–2627
    - urinary retention, postoperative, 2629–2630
    - Wernicke encephalopathy, 2631
    - Williams-Beuren syndrome, 2631–2632
- Neuroplasticity, in lower urinary tract dysfunction, 2600–2602
- Neurospinal abnormalities, with cloacal exstrophy, 574–575, 574*f*
- Neurospinal dysraphism, lower urinary tract dysfunction with, 2617–2619
- Neurotransmitters, within brainstem networks, 2495–2496
- Neurovascular bundle (NVB)
    - injury, complications of seminal vesicle surgery, 1864
    - preservation of, in laparoscopic radical prostatectomy, 3575–3576, 3575*f*–3576*f*
    - in retropubic radical prostatectomy, 3555–3556
        - high anterior release of, at apex, 3557–3558, 3558*f*–3559*f*
        - identification of, 3556–3558
        - preservation of, 3556–3557, 3556*f*–3557*f*

wide excision of, 3558, 3559*f*

Neutrons, 3594

NGF, Nerve growth factor

NHCT, Noncontrast helical computed tomography

Nicardipine, for PD, 1612, 1617*t*

Nicotinic agonists, ureteral response to, 1887

Nifedipine

- for BPS/IC oral therapy, 1241*t*, 1243
- for ureteral relaxation, 1900

Nighttime, definition of, 2666

Nilutamide, 3675–3676

Nintedanib, for RCC, 2337–2338

Nipple (rosebud) stoma, 3182, 3182*f*–3183*f*

Nipple valve, 3191, 3192*f*

- for continent urinary diversions, 707

NIRS, Near-infrared spectroscopy

Nitric oxide (NO)

- bladder afferent pathway and, 2484, 2484*f*
- in ED, 1494, 1495*t*, 1497–1498
- to facilitate bladder emptying, 2720.e1
- metabolism of, in BPS/IC etiology, 1232.e9
- and PD, 1605
- renal vascular tone control by, 1913
- ureteral response to, 1886, 1886*f*
- urothelium release of, 2469

Nitrite, 437

Nitrite tests, in urine, 20–21, 20*f*

Nitrofurantoin, 441

- for UTIs, 1150–1153, 1151*t*–1153*t*, 1156, 1163, 1187*t*

Nitrous oxide, as insufflant choice, 220

NK_1-receptor antagonists, to facilitate bladder filling and urine storage, 2713.e4

Nkx3.1, 3276

NLUTD, Neurogenic lower urinary tract dysfunction

NMIBC, Non-muscle-invasive bladder cancer

NO, Nitric oxide

No drainage tube, 176

Nocturia, 2581, 2664–2678, 3345

- behavioral therapy with urge suppression for, 2727
- bladder capacity and, 2667, 2668*t*, 2671–2674
- classification of, 2667, 2668*t*, 2669*f*
- definition of, 2664, 2665*t*
- degree of bother of, 2664
- drug effects causing, 2671*b*
- evaluation of, 2666–2667, 2667*b*, 2678*b*
- in geriatric patients, 2920.e8–2920.e9
- mechanisms of, 2505
- mortality, early and, 2664–2666
- nocturnal polyuria and, 662, 2667–2668, 2668*t*
- overactive bladder and, 2637
- polyuria and, 2667–2668, 2668*t*
- prevalence of, 2461, 2664
- rationale for evaluation and management of, 2664–2666, 2666*b*
- societal costs of, 2666
- treatment algorithm for, 2669*f*

Nocturia Quality of Life (N-QoL) score, 2669

Nocturnal bladder capacity index (NBCi), 2667

Nocturnal detrusor overactivity (NDO), 2671

Nocturnal enuresis, 2539, 2581

- desmopressin for, 2712
- treatment of, 2547

Nocturnal polyuria

- diminished bladder capacity and, 2674–2678
- epidemiology and causes of, 2667–2668, 2670*f*
- management of, 2668–2671, 2673*t*
- nocturia and, 662, 2667–2668, 2668*t*
- with obstructive sleep apnea, 2668

Nocturnal polyuria index (NPi), 2667

Nocturnal urine volume (NUV), 2667

Node-positive disease, outcomes of prostatectomy for, 3647–3648

Nonabsorbable sutures, 150

Non-AIDS-defining urologic malignancies, 1268

Nonatherosclerotic renal artery diseases, 1933–1934

Noncommunicating hydroceles, epidemiology and pathogenesis of, 889

Noncontrast computed tomography (NCCT), of urinary calculi, 2037, 2037*f*

Noncontrast helical computed tomography (NHCT), for urinary tract obstruction, 779

Nondilated or absent bladder, 518–519
- bladder agenesis, 518–519
- bladder hypoplasia, 519
- cloacal and bladder exstrophy, 519

Nondismembered pyeloplasty, for ureteropelvic junction obstruction in children, 828–829, 829*f*–831*f*

Nonfilarial parasitic infections, of genitourinary tract
- amebiasis, 1332
- echinococcosis, 1332
- enterobiasis, 1332
- trichomoniasis, 1332

Nonfocal extraprostatic extension, 3511

Nonglomerular hematuria, 17–18

Nongonococcal urethritis, 1253, 1254*f*
- *Chlamydia*, 1253

- *Mycoplasma genitalium*, 1253–1254
- recurrent and persistent, 1254
- *Trichomatis vaginalis*, 1254

Noninfectious genital ulcers, 1286–1288, 1286*b*
- aphthous ulcers and Behçet disease, 1286–1287, 1287*f*
- pyoderma gangrenosum, 1287–1288, 1288*f*
- traumatic causes, 1288, 1288*f*

Nonionizing radiation, technique of, 403, 403*b*

Nonmaleficence, definition of, 115

Nonmonosymptomatic enuresis, 660

Non-muscle-invasive bladder cancer (NMIBC), 3075
- Bacille Calmette-Guérin for, 3099–3100
  - carcinoma treatment in situ with, 3100
  - contraindications to, 3102*b*
  - mechanism of action of, 3100
  - prophylaxis to prevent recurrence, 3100–3101
  - residual tumor treatment, 3100
  - toxicity management of, 3102*b*
- biology of, 3092–3094
- early cystectomy for, 3106–3107, 3107*b*
- endoscopic surgical management of, 3094–3098, 3099*b*
  - confocal laser endomicroscopy for, 3097–3098
  - fluorescence cystoscopy for, 3097–3098, 3098*f*
  - laser resection for, 3097
  - narrow band imaging for, 3097–3098
  - office-based, 3097
  - optical coherent tomography for, 3097–3098
- immunotherapy for, 3099–3103, 3103*b*
  - Bacille Calmette-Guérin, 3099–3100
  - interferon, 3102–3103
  - investigational, 3103
- intravesical chemotherapy for, 3103–3105, 3104*t*, 3105*b*
  - combination therapy, 3105
  - doxorubicin, 3103–3104
  - mitomycin C, 3104–3105
  - novel agents, 3103
  - to prevent implantation, 3103–3105
  - to prevent tumor implantation, 3100*b*

- thiotepa, 3103
- valrubicin, 3104
- intravesical immunotherapy for, 3099–3103
  - Bacille Calmette-Guérin, 3099–3100
- intravesical therapy of, 3098–3105
- management strategies for, 3091–3111
- pathology of, 3092*t*, 3094*b*
  - characteristics by stage, 3094, 3094*t*
- perioperative intravesical therapy for, 3098–3099
- prevention of
  - secondary, 3110
  - surveillance for, 3107–3110, 3108*t*, 3111*b*
- refractory high-grade disease, 3105–3107
  - alternative options for, 3106
  - management of, 3106, 3107*b*
- surveillance for, 3108–3109
  - cystoscopic, 3108–3109
  - extravesical, 3110
  - tumor markers, 3109–3110, 3109*f*
  - urine cytology, 3109
- transurethral resection for
  - complications of, 3096
  - repeat, 3096–3097

Non-rapid eye movement (NREM), 2665

Nonrefluxing ureteral reimplantation, 3021–3022, 3022–3025, 3022*f*–3024*f*

Nonselective α_1-blockers, 3356

Nonseminoma germ cell tumors (NSGCTs), 2227–2229
- chemotherapy for, 1695, 1696*t*, 1697
- clinical stage I tumors, 1693–1696, 1694*t*
  - retroperitoneal lymph node dissection, 1694–1695, 1695*t*
  - risk assessment, 1693
  - surveillance, 1693–1694, 1694*t*
  - treatment selection for, 1695–1696
- clinical stage IIA and IIB, 1696–1697
- clinical stage IIC and III tumors, 1697–1700
- clinical stage IS, 1696
- genomic alterations in, 1361
- relapse after, 1701–1702

  - residual mass management after, 1698–1700, 1698*t*–1699*t*
  - treatment of, 1692, 1692*b*, 1702*b*

Nonstaghorn renal calculi, 2069–2070
  - stone burden of
    - between 1 and 2 cm, 2073–2074, 2073*f*
    - greater than 2 cm, 2074
    - up to 1 cm, 2072–2073, 2072*b*

Nonsteroidal antiandrogens, 3674–3676

Nonsteroidal anti-inflammatory drugs (NSAIDs)
  - RI and, 778
  - for urinary tract obstruction, 795

Nonsurgical focal therapy, of renal tumors, 2309–2323
  - complications, 2318–2319, 2320*f*–2321*f*, 2320*b*
  - cryoablation, 2309–2310, 2310*b*, Cryoablation (CA), for renal tumors
  - new ablation modalities, 2319–2323, 2323*b*
  - oncologic outcomes, 2314–2318, 2315*t*–2316*t*, 2318*b*
  - radiofrequency ablation, 2310–2312, 2312*b*
  - surgical technique, 2312
  - treatment success and follow-up protocol after tumor ablation, 2312–2314, 2314*b*

Nontreponemal syphilis tests, 1258

Nontuberculous mycobacteria, 1133

Nonulcerating skin infections, HIV and, 1265

Nonurothelial malignant lesions, 2189
  - adenocarcinoma, 2189
  - other, 2189
  - squamous cell carcinoma, 2189

Norephedrine, for stress urinary incontinence in women, 2714

Norepinephrine
  - in ED, 1494, 1495*t*
  - renal vascular tone control by, 1913
  - ureteral response to, 1888

Normal compliance, 2560–2561

Normal detrusor function, 2565

Normal-pressure hydrocephalus, lower urinary tract dysfunction with, 2604

Normal scrotal position, 949

Normocomplemententemic glomerulonephritis, 346–348

Normothermia, definition of, 145

North American and International Finasteride trial, 3372

Nosocomial UTIs, 433

NOTES, Natural orifice transluminal endoscopic surgery

Novel markers, for locally advanced prostate cancer, 3642–3643, 3642*t*

NPi, Nocturnal polyuria index

NPO guidelines, 449, 449*t*

- enteral tube feeds, 449
- ketogenic diet, 449
- special, 449

NR0B1 gene, 992*f*, 992*t*, 993

NR5A1 gene, 992–993, 992*f*, 992*t*

NREM, Non-rapid eye movement

NS-398, urethral function effects of, 1903

NSAIDs, Nonsteroidal anti-inflammatory drugs

NSF, Nephrogenic systemic fibrosis

NSGCTs, Nonseminoma germ cell tumors

NTD, Neural tube defects

Nuclear cystography, 389–390

Nuclear imaging, 806, 806*f*

Nuclear localization, of androgen receptors, 3291

Nuclear matrix, androgens in, 3294–3295

Nuclear medicine

  basic principles of, 91–100
  imaging agents in, 91
  in urologic oncology, 42–44

Nuclear renography, for urinary tract obstruction, 779

Nuclear scintigraphy, 40–44, 44*b*

Nucleation, 2011

Nucleic acid amplification tests (NAATs), for genitourinary tuberculosis, 1310

Nucleotide excision repair (NER), 1351.e1, 1351.e1*f*

Nucleotides, 1346.e1, 1346.e2*f*

Numeric pain rating scale, 448*f*

Nurses' Health Study, 2710

Nursing Home Setting, urinary incontinence in, 2919–2920

Nutcracker syndrome, 1869–1870

Nutrition, urinary intestinal diversion and, 3203

Nutritional status, in urologic surgery, 122–123

NUV, Nocturnal urine volume

NVB, Neurovascular bundle

NX-1207, to facilitate bladder filling and urine storage, 2713.e2

O

OAB, Overactive bladder

Obesity, 1418–1419
  abdominal, 1418–1419
  benign prostatic hyperplasia and, 3324, 3325*t*
  and ED, 1504
  hyperoxaluria and, 2059–2060
  as laparoscopic and robotic surgery contraindication, 203
  laparoscopic kidney surgery and, 2279
  midurethral sling outcomes with, 2863, 2863*b*

- morbid, percutaneous nephrolithotomy and, 2106–2107
- orthotopic urinary diversion and, 3238
- prostate cancer and, 3465, 3465*f*, 3544
- in retropubic suspension surgery, 2756
- upper urinary tract calculi and, 2089
- urinary incontinence and, 2585–2586, 2734

Objective structured assessment of technical skills (OSATS) tool, 470

Obstetric fistulae, 2925–2926, 2926*f*

Obstetric history, pelvic floor disorders and, 2527–2528

Obstructed hemivagina and ipsilateral renal agenesis (OHVIRA) syndrome, 327, 328*f*

Obstructed labor injury complex, 2925

Obstruction
- bladder
  - response to, 3315–3316
  - RMS causing, 1113
- of seminal vesicles and ejaculatory ducts, 1407
- ureteropelvic junction, Ureteropelvic junction obstruction
- urinary tract, Urinary tract obstruction
- in UTI host defense mechanisms, 1139

Obstructive sleep apnea (OSA), 1420
- metabolic syndrome and, 1420
- nocturnal polyuria with, 2668
- treatment of, 2920.e8

ObTape, 2851

Obturator internus, 2448–2449, 2449*f*

Obturator lymph node, 1380

Obturator lymphadenectomy, 3149, 3152*f*

Obturator nerve, 2453*t*

OBTX, OnabotulinumtoxinA

Occult spinal dysraphism, 389

“Occult” stress urinary incontinence, 2591–2592

Occupation

- patient history of, 9
- renal calculi and, 2007–2008

Occupational exposures, UTUC risk and, 2186

Occupational risk, in bladder tumor, 3076, 3076*t*

Odd-skipped related 1 *(Osr1)*, vesicoureteral reflux and, 491.e1

ODS, Output display standard

Off-clamp partial nephrectomy, 2303

Ogilvie syndrome, with intestinal anastomoses, 3181

Olaparib, 3702

Older women, prevention of urinary incontinence and, 2735

Oligohydramnios, prenatal sonogram for, 409*f*

Oligomeganephronia, 742–744, 743*f*

Oliguria, 386, 461

Omental herniation, 468–469

OnabotulinumtoxinA (OBTX), 286

- to facilitate bladder filling and urine storage, 2707–2708
- neuromodulation with, 2512
- in surgical management of voiding dysfunction, 2848
- for UUI, 2546

Oncocytoma, 2391, 2392*b*

- renal, 2123–2125, 2125*b*
    - epidemiology and etiology of, 2123
    - evaluation of, 2124
    - management of, 2124–2125
    - pathophysiology of, 2123–2124, 2124*f*

Oncogenes, 1346–1347, 1347*b*

Oncologic fistulae, 2959

Oncology

- chronic inflammation in GU cancers, 1336, 1338*b*
    - bladder cancer, 1336–1338, 1337*f*–1338*f*
    - kidney cancer, 1338
    - prostate cancer, 1338
- immunologic response in GU cancers, 1333–1345, 1336*b*
    - adaptive immune system, 1334–1336, 1335*f*
    - immune editing hypothesis, 1336, 1337*f*
    - innate immune system, 1333–1334, 1334*f*–1335*f*, 1334*t*–1335*t*
- immunotherapy for GU cancers, 1333–1345, 1341*b*, 1343*b*
    - BCG in bladder cancer, 1333, 1334*f*, 1338–1339, 1339*f*
    - cancer vaccines, 1339–1340, 1340*f*–1341*f*
    - combination, 1343–1345, 1345*f*
    - immune checkpoint blockade, 1342, 1342*f*
- molecular genetics in, Molecular genetics
- pediatric, Pediatric oncology

Oncotype DX Prostate Cancer Test, 3488, 3521

One-kidney, one-clip model, of renovascular hypertension, 1917, 1918*f*

One-port catheters, 153

On-table intravenous pyelography, for pediatric genitourinary trauma, 1073–1074

Open access techniques
- for achieving extraperitoneal access and developing extraperitoneal space, 210–211
- for achieving retroperitoneal access and developing retroperitoneal space, 209–210
- for achieving transperitoneal access and establishing pneumoperitoneum, 209, 209*f*
- complications related to, 224

Open adrenalectomy, 2410–2414
- anterior transabdominal approach, 2412–2413, 2412*f*–2413*f*
- flank retroperitoneal approach, 2410–2411, 2410*f*–2411*f*
- left, 2412–2413, 2412*f*–2413*f*
- outcomes, 2421–2423
- posterior lumbodorsal approach, 2411–2412, 2411*f*–2412*f*
- thoracoabdominal approach, 2413–2414, 2413*f*–2414*f*

Open cystotomy, 156, 156*f*

Open distal ureterectomy with excision of bladder cuff, 2204

Open flank incision, 459*f*

Open nephrectomy, technique of, for benign diseases, 2254, 2254.e1*f*

Open prostatectomy, robotic prostatectomy *versus*, 3532

Open radical prostatectomy, 3548–3565

Open reconstruction, for urethral stricture disease, 1819–1828

Open segmental ureterectomy, 2207, 2208*f*–2209*f*

Open simple prostatectomy, 3450

- incision for, 3450
- patient positioning for, 3450
- space of Retzius development for, 3450

Open surgery, common urologic procedures, antimicrobial prophylaxis for, 1199–1200

Open transabdominal orchidopexy, 967

Operating room setup, for laparoscopic and robotic surgery, 205, 205*b*

Operative nerve injury, 262

Operative team placement, for laparoscopic and robotic surgery

- retroperitoneal upper abdominal procedures, 207, 207*f*
- transperitoneal upper abdominal procedures, 206*f*, 206.e1*f*

Opiates, and ED, 1509

Opioid-receptor antagonists, to facilitate bladder emptying, 2719

Opioids

- abuse, in men, 1426
- and ED, 1494–1495, 1495*t*
- for urinary tract obstruction, 795

Oral mucosa grafts, for urethral and penile reconstruction, 1806, 1806*f*

Oral therapies, for BPS/IC treatment, 1241–1244, 1241*t*, 1244*b*

Orchalgia, 1219–1220

- nonmedical therapy for, 1221
- nonradical surgical treatments, 1221

surgical therapy, 1221–1222

Orchidopexy

Fowler-Stephens, 967–968

laparoscopic, 967–968

open transabdominal, 967

for prune-belly syndrome, 593–594

transscrotal, 967, 967*f*

Orchiectomy, 3674

castration-resistant prostate cancer and, 3688

for chronic scrotal pain syndrome, 1222

delayed, 1712

evaluation after, 1712

partial, Partial orchiectomy

radical, Radical orchiectomy

simple, 1848

technique of, 1848, 1849*f*

for TGCTs, 1686

Orchiopexy, in adults, 1483–1484, 1483*f*

Orchitis, 1440

acute, 1202–1223

Orciprenaline, ureteral response to, 1888

Organ Injury Severity Scale for Kidney, of AAST, 1992*t*

Organ ischemia, during vena caval thrombectomy, 2278

Organ preservation, in penile cancer management, 1751

Organ transplantation, Transplantation

Organomegaly, as laparoscopic and robotic surgery contraindication, 204

Organ-sparing therapy, UTUC after, 2220

Orgasm, female sexual dysfunction and, 1637

Orgasmic headache, 1580–1581

Orteronel, 3695

Orthophosphate, for hypercalciuria, 2052–2053

Orthostatic proteinuria, 343–344

Orthotopic Mainz pouch, for orthotopic urinary diversion, 3246, 3248*f*

Orthotopic neobladder, 3178

Orthotopic urinary diversion, 3233–3257

- basic principles of, 3234–3235, 3235*b*
- bladder substitution in
    - bowel segment selection for, 3241–3249, 3242*b*
    - reflux prevention in, 3241–3242, 3242*b*
- complications of, 3249–3257
- continence mechanism in, 3239, 3241*b*
- continence preservation in
    - anterior apical dissection in male patient, 3239–3240
    - urethra preservation in female patient, 3240–3241, 3240*f*
- follow-up for, 3255, 3255*b*
- general perioperative management for, 3242–3243
- history of, 3233–3234, 3234*f*, 3234*b*
- oncologic factors for, 3235–3237, 3237*b*
    - locally advanced tumor stage, 3237
    - urethral recurrence risk in men, 3235–3236
    - urethral recurrence risk in women, 3236
- patient selection for, 3235–3239, 3235*f*
    - patient-related factors, 3237–3239, 3239*b*
- quality of life after, 3255–3257, 3256*t*, 3257*b*
- results with, 3249–3257
    - continence in, 3251–3254, 3252*t*–3253*t*, 3254*b*
    - urinary retention with, 3254, 3254*b*
- surgical techniques for, 3243–3246
    - Camey II, 3243, 3243*f*
    - colon and ileocolic pouches, 3246–3248
    - ileal neobladder, 3245, 3246*f*
    - ileal reservoirs, 3243
    - Kock ileal reservoir, 3243–3244, 3244*f*
    - minimally invasive, 3248–3249
    - orthotopic Mainz pouch, 3246, 3248*f*
    - Padua pouch, 3248, 3250*f*
    - right colon pouch, 3246
    - serous-lined extramural tunnel, 3244–3245, 3245*f*

        - sigmoid pouch, 3248, 3249*f*
        - Studer pouch, 3245, 3247*f*
        - T pouch modification, 3245–3246, 3247*f*

OSA, Obstructive sleep apnea

Osmolality, 15

Osmotic effect, of urothelium of bladder, 2467

Osteogenic sarcoma, of kidney, 2181

Osteomalacia, with urinary intestinal diversion, 3201–3202

Osteopontin, in crystal formation, 2011, 2014–2015

Osteoporosis, hormonal therapy and, 3680

Osteotomy

- for classic bladder exstrophy, 540–542, 541*f*–542*f*
    - complications of, 542–543
- in urinary tract reconstruction, of cloacal exstrophy, 578–579, 579*f*

Ouabain, urethral function effects of, 1903

Outcomes research, 101

- measure, 101–102
- overall mortality in, 102–103
- proxy endpoints, 104
- recurrence, 104–105
- sexual dysfunction, 110–112
- short-term, 105–108

Outflow resistance, 682

Output display standard (ODS), in ultrasonography, 78

Ovarian formation, 318

Ovarian tumors, in pediatric patients, 1120

Ovariectomy, 3063–3064

Ovaries
- anatomy of, 324*f*, 2437–2438
- function of, 995
- ligament of, 321

Overactive bladder (OAB), 1421, 2637–2649, 2915
- afferent mechanisms in, 2641–2642
- after retropubic suspension surgery, 2770
- clinical assessment of, 2643–2646, 2646*b*
  - advanced evaluation, 2645–2646, 2645*f*–2646*f*
  - initial evaluation, 2643–2645, 2644*t*
  - laboratory examination, 2645
  - physical examination, 2645
- costs of, 2640
- definitions for, 2637, 2638*f*, 2638*t*, 2639*b*
- detrusor overactivity with, 2640
- economics of, 2638–2640
- epidemiology of, 2638–2640, 2639*t*
- estrogens for, 2709–2710, 2713–2714
- etiology of, 2643, 2643*b*
- female sexual dysfunction and, 1655–1656
- health burden of, 2639–2640
- incidence and progression of, 2639
- management of, 2646–2649, 2649*b*
  - approach, 2647–2649, 2648*f*
  - first-line therapy, 2646–2647
  - fourth-line therapy, 2647
  - second-line therapy, 2647
  - third-line therapy, 2647
- mechanisms of, 2504, 2713.e4*b*
- metabolic syndrome and, 1421
- neuromodulation for, 2510
  - rationale for, 2511, 2511*f*
- nocturnal bladder capacity and, 661–662
- pathophysiology of, 2517, 2640–2643, 2640*f*–2641*f*, 2643*b*

- pelvic organ prolapse and, 2591
- pharmacologic therapy for, 2682*t*, 2704*b*
  - antimuscarinic agents, 2681, 2681*f*
- prevalence of, 2591, 2638–2639
- questionnaires for, 2532*t*–2533*t*
- sacral nerve stimulation for, 2752–2753
- terminology for, 2637, 2638*f*, 2638*t*, 2639*b*
  - bladder pain syndrome distinguished from, 2637, 2638*f*
  - mixed symptoms incorporating urinary urgency, 2637, 2638*f*
- urgency urinary incontinence with, 2539

Overactive Bladder Questionnaire (OAB-Q), 111*t*

Overflow incontinence, patient history of, 5–6

Overflow proteinuria, 18

Overnight low-dose dexamethasone suppression test, in evaluation of adrenal masses, 2400

Overnight water deprivation test (OWDT), 2678

Ovotesticular disorder of sexual development, 322, 323*f*, 999*f*, 1006–1007

OWDT, Overnight water deprivation test

Oxalate

- in calcium stone formation, 2020
- foods containing, 2057*b*
- metabolism of, 2016–2017

Oxalobacter formigenes, 2017

Oxford guidelines

- for behavior therapy, 2722.e4*b*
- to facilitate bladder filling and urine storage, 2681*t*

Oxidative stress, stone disease and, 2013–2014

Oxidized regenerated cellulose agents, 147

Oxybutynin, 2498, 2499*t*, 3381

- for urinary incontinence, 657

Oxybutynin chloride

effects on cognition of, 2695
extended release, 2693–2694
to facilitate bladder filling and urine storage, 2682, 2682*t*
with α-adrenoreceptor antagonists, 2705
with other antimuscarinics, 2693
immediate-release, 2693
intravesical administration of, 2695
rectal administration of, 2695
topical gel, 2694
transdermal, 2694

Oxygen free radicals and oxidative stress, and PD, 1605

Oxytocin
in ED, 1494, 1495*t*
for female orgasmic disorder, 1648
for female sexual arousal disorders, 1650

Oxytocin antagonists, for PE, 1572.e2

P

P (mannose-resistant) pili, 429, 1134–1135

p16, INK4A gene

Pacemaker activity, 1881–1882, 1882*f*

Pacemaker potentials, 1881–1882, 1882*f*

Packed red blood cells, for urologic surgery, 147

Paclitaxel, for non-muscle-invasive bladder cancer, 3105

Paclitaxel, ifosfamide, and cisplatin (TIP)
for NSGCTs, 1700
for penile cancer, 1770

Pad tests
for male urinary incontinence, 2541–2543
for pelvic floor disorders, 2531–2533
use of, 109–110

PADAM, Partial androgen deficiency in aging male

Padua pouch, for orthotopic urinary diversion, 3248, 3250*f*

Pagano technique, in urinary diversion, 3186–3187, 3187*f*

Pain

- after laparoscopic and robotic surgery, 230–231
- after midurethral sling, 2870–2871
- in castration-resistant prostate cancer, 3702, 3703*t*
- definition of, 448
- intensity of, 448*f*
- management of, Analgesia
  - after laparoscopic radical prostatectomy, 3578–3579
  - in urinary tract obstruction, 795
- patient history of, 2–3
- ureteral anomalies and, 802

Painful orgasm, 1636

Paired box gene 2 *(PAX2),* vesicoureteral reflux and, 491.e1

Palliative care, 2922

Palliative surgery, for metastatic RCC, 2328, 2328*b*

Palpable testis, surgical management of, 966–967

- inguinal orchiopexy, 966–967
- transscrotal orchidopexy, 967, 967*f*

Pampiniform plexus, 1372, 1372*f*–1373*f*, 1393

Pancreas, 1668, 1668.e2*f*, 1669*f*–1670*f*

Pancreatic injury

- during laparoscopic and robotic surgery, 230.e1
- during radical nephrectomy, 2261

Panurothelial disease, UTUC, 2194

Papaverine, 1535

Papillary adenoma, of kidney, 2128, 2128*b*

Papillary necrosis, hematuria and, 18

Papillary RCC
  molecular genetics of, 1354*t*, 1358
  pathology of, 2149*t*–2151*t*, 2152, 2153*f*
Papillary urothelial neoplasm of low malignant potential (PUNLMP), 3083–3084, 3083*f*, 3092
Papilloma
  of bladder, 3081, 3081*f*
  of upper urinary tract, 2188
Papulosquamous disorders, 1278–1283, 1278*b*
  fixed drug eruption, 1282, 1283*f*
  lichen nitidus, 1281
  lichen planus, 1280–1281, 1281*f*
  lichen sclerosus, 1281–1282, 1282*f*
  psoriasis, 1278–1279, 1279*f*
  reactive arthritis, 1279–1280, 1280*f*
  seborrheic dermatitis, 1282–1283
Paracolpium, 2438
Paradoxical incontinence, Overflow incontinence
Paraganglioma
  of adrenal gland, 2235, 2235*f*
  of bladder, 3038–3039, 3039*f*
Paraganglionic system tumors, retroperitoneal tumors and, 2235, 2235*f*
Parameatal urethral cyst, 394, 882, 882*f*
Parametrium, 2438
Paraneoplastic syndromes, in RCC, 2156
Paranephric fat, 1865–1866
Parapelvic cyst, 775, 775*f*
Paraphimosis, 393, 871–872, 872*f*
Paraphimosis, urethral reconstructive surgery for, 1811
Pararenal space, anterior, 1668, 1668.e1*f*–1668.e2*f*

Parasites, in urine, 24, 25*f*

Parasitic infections, of genitourinary tract, 1319–1332

- filariasis, 1328–1331, 1332*b*
    - diagnosis, 1330
    - epidemiology, 1328–1329
    - organisms, 1328, 1328*f*
    - pathology and clinical manifestations, 1329–1330, 1329*f*–1330*f*
    - prevention and control, 1331
    - treatment, 1330–1331
- nonfilarial
    - amebiasis, 1332
    - echinococcosis, 1332
    - enterobiasis, 1332
    - trichomoniasis, 1332, Trichomoniasis
- schistosomiasis, 1319–1328, 1328*b*
    - biology and life cycle, 1319, 1320*f*–1321*f*
    - clinical manifestations, 1324
    - diagnosis, 1325–1326, 1325*f*–1326*f*
    - epidemiology, 1319–1321
    - history, 1319
    - pathogenesis and pathology, 1321–1324, 1321*f*, 1323*f*
    - prevention and control, 1327–1328
    - prognosis, 1327
    - treatment, 1326–1327

Parasympathetic blocking agents, ureteral response to, 1888

Parasympathetic decentralization, LUTD and, 2620–2621

Parasympathetic nervous system

- in retroperitoneum, 1675
- in ureteral function, 1887–1888

Parasympathetic pathways, of lower urinary tract, 2480, 2480*f*

Parasympathetic transmission, in neural control of LUT, 2593

Parasympathomimetics

- for detrusor underactivity, 2660–2661
- to facilitate bladder emptying, 2716–2718

Paratesticular cancer, RMS in pediatric patients, 1126–1127, 1127*b*

- outcomes of, 1126–1127

- presentation and staging of, 1126
- RPLND role in, 1126
- treatment of, 1126

Parathyroid hormone (PTH)
- in calcium metabolism, 2016
- in renal hypercalciuria, 2019
- renal regulation of, 1914, 1914*f*
- in resorptive hypercalciuria, 2020

Paraureteral congenital diverticula, 522, 522*f*

Paraureteral diverticula, 525

Paraurethral cysts, 394*f*, 395, 397*f*, 976–977, 977*f*

Paravaginal repair procedures
- for female incontinence, 2766–2767, 2767*b*
  - Burch colposuspension *versus*, 2773
  - results with, 2766–2767
  - suspensions in, configuration of, 2758
  - technique for, 2766, 2767*f*
  - tissue approximation in, 2759
  - urethral elevation in, 2758
- for pelvic organ prolapse
  - abdominal, 2779, 2780*t*
  - vaginal, 2780*t*, 2783, 2784*f*–2785*f*

Parenchymal compression, for laparoscopic partial nephrectomy, 2303–2304

Parental counseling for fetal intervention, 362

Parity, urinary incontinence and, 2583

Parkinson disease (PD)
- detrusor underactivity and, 2657
- diagnosis of, 2605
- in ED, 1502
- lower urinary tract dysfunction with, 2605–2606
- pathophysiology of, 2605
- treatment for, 2605

Paroxetine hydrochloride, to facilitate bladder filling and urine storage, 2702

Partial adrenalectomy, 2421, 2421*b*

Partial androgen deficiency in aging male (PADAM), 1392

Partial colpocleisis, for apical pelvic organ prolapse repair

- results with, 2812–2814
- technique for, 2811–2812, 2811*f*–2812*f*

Partial cystectomy, 3038–3043

- evaluation for, 3038–3040
- extraperitoneal approach to, 3040–3041
- for muscle-invasive bladder cancer, 3124–3125
- open, 3040
- outcomes with, 3042–3043
- surgical indications for, 3038–3040
- surgical technique for, 3040–3041
- transperitoneal approach to, 3041–3042, 3042*f*–3043*f*
- with transurethral resection of bladder tumor, 3143, 3144*f*

Partial gonadal dysgenesis, 1004

Partial nephrectomy (PN)

- for benign diseases, 2254, 2255*f*
- laparoscopic, Laparoscopic partial nephrectomy
- for malignancy, 2261–2266, 2262*f*
  - complications of, 2265–2266
  - enucleation for small cortical tumors, 2263, 2264*f*
  - preoperative considerations for, 2262–2263, 2262*f*–2263*f*, 2263.e1*f*
  - segmental nephrectomy for large polar tumors, 2263–2264, 2263.e1*f*–2263.e2*f*, 2264.e1*f*, 2265*f*
  - wedge resection for large cortical tumors, 2263, 2265*f*
- for RCC, local recurrence after, 2164–2169, 2165*b*, 2167*t*, 2169*f*
- for renal injuries, 1989–1990, 1989*f*
- for Wilms tumor, 1107–1108

Partial orchiectomy, 1712

- technique for, 1712
- for TGCT, 1686–1688

Partial prostate ablation, 3624

Partial scrotectomy, 1844–1845, 1846*f*

Partial transection, for lower ureteral injuries, 1999

Partial ureteral obstruction (PUO), hemodynamic changes with, 792

Partial urogenital mobilization (PUM), 1033–1034, 1034*f*–1036*f*

Partin tables, 3527–3528

Past surgical history, 7

Patch cavoplasty, for IVC, 2276, 2277*f*

Patch electromyography, 483

Patent urachus, 523–525, 524*f*

Pathogenesis

- of bacteriuria in pregnancy, 1185
- UTI, 1131–1140, 1140*b*
    - alterations in host defense mechanisms, 1139–1140
    - bacterial virulence factors, 1133–1134
    - early events in UPEC pathogenesis, 1134–1135, 1134*f*
    - epithelial cell receptivity, 1135–1137
    - fastidious organisms, 1133
    - natural defenses of urinary tract against, 1137–1139
    - phase variation of bacterial pili in vivo, 1135.e1, 1135.e1*f*
    - routes of infection, 1131
    - urinary pathogens, 1132, 1133*f*

Patient, Geriatric patients, Pediatric patients

Patient biases, of localized prostate cancer, 3525

Patient counseling, of localized prostate cancer, 3532–3535, 3532*f*

Patient decision making, 118, 118*f*

Patient growth, after augmentation cystoplasty, 698

Patient history, 1–9

- chief complaint, 1
- medical history, 7–9
- overview, 1
- physical examination, 9–12
- of present illness, 1–7
- special populations, 12–13

Patient positioning, 205
  for laparoscopic and robotic surgery, 205*f*
    hemodynamic effects related to, 222
  for laparoscopic kidney surgery, 2279–2285
    hand-assisted laparoscopy, 2281–2282, 2283*f*
    laparoendoscopic single-site surgery and natural orifice transluminal endoscopic surgery, 2284–2285, 2285*f*, 2286*t*
    retroperitoneal, 2279–2281, 2282*f*
    robotic-assisted laparoscopy, 2282–2284, 2284*f*–2285*f*
    transperitoneal, 2279, 2280*f*–2281*f*
  for laparoscopic radical prostatectomy, 3568, 3569*f*
  for open simple prostatectomy, 3450
  for prostate biopsy, 3497
  for robot-assisted laparoscopic simple prostatectomy, 3454
Patient preparation
  for cystourethroscopy, 187–190, 189*t*
  for surgery, Preoperative care
  for ureteroscopy, 199–200
  for urodynamic studies, 2552
Patient safety, in ultrasonography, 77–78
Patient selection
  for brachytherapy, 3599
  for focal therapy for prostate cancer, 3620–3621
  for prostate cancer, 3540–3541
Patient-physician relationship, in intraoperative consultation, 296
Patient-reported outcome measures, for male urinary incontinence, 2541, 2541.e1*f*–2541.e2*f*, 2542*f*
Patient-reported outcomes, 108–113, 110*t*, 476
  methods of assessing, 108–109
  selecting an appropriate, 477
  tools for use in females with sexual dysfunction, 112*t*
  tools for use in men with sexual dysfunction, 112*t*
  tools for use primarily in women with urinary incontinence, 111*t*
Pazopanib, for RCC, 2179*t*–2180*t*, 2335–2336
PBR, Peripheral benzodiazepine receptor

PBS, Prune-belly syndrome

PCA3, Prostate cancer antigen 3

PCI, Protein C inhibitor

PCN, Percutaneous nephrostomy

PCPT, Prostate Cancer Prevention Trial

PCr, Plasma creatinine

PC-RPLND, Postchemotherapy retroperitoneal lymph node dissection

PCS, Post-chemotherapy surgery

PD-1, Programmed death-1

PDE5-I, Phosphodiesterase type 5 inhibitors

PDT, Photodynamic therapy

Pearly penile papules, 1302, 1303*f*

Pectus excavatum, 587*f*, 600

Pediatric ACC, 2388

Pediatric catheters, size of, 153*t*

Pediatric genitourinary trauma, 1065–1086

- assessment of
    - computed tomography for, 1066
    - focused assessment with sonography for trauma, 1066
    - renal trauma grading system for, 1066–1072, 1067*f*–1069*f*, 1067*t*, 1069*t*
    - renal ultrasonography for, 1066
- bladder injuries, 1080–1083, 1080*t*, 1083*b*
    - imaging of, 1080
    - management, 1080–1081
    - pelvic fracture of, 1080
    - presentation of, 1080
- blunt *versus* penetrating, 1069
- genital injury in, 1083–1086, 1086*b*
- indications for renal imaging for, 1065, 1066*t*
- management of, 1069–1070
    - angioembolization of isolated renal segment, 1072
    - chronic flank pain, 1078

        - chronic kidney disease, 1078
        - congenital anomalies and renal injuries, 1075–1076
        - control of renal vasculature, 1074
        - early repeat imaging, 1070
        - follow-up and activities with solitary kidney, 1078
        - follow-up and long-term issues, 1076, 1078*b*
        - fusion anomalies and ectopic kidney, 1076, 1077*f*
        - hypertension, 1077–1078
        - late repeat imaging and assessment of renal function, 1077
        - nephrostomy tube, 1072
        - nonoperative, 1070, 1073*b*
        - on-table intravenous pyelography or ultrasonography, 1073–1074
        - operative, 1073–1078, 1076*b*
        - percutaneous drain, 1071–1072, 1072*f*
        - persistent urine leak, 1070, 1071*f*
        - reconstruction *versus* nephrectomy, 1074
        - renal arterial laceration, 1074
        - renal arterial occlusion, 1074
        - renal exploration, 1073
        - renal exploration with repair of urine leak, 1072
        - renal pelvis rupture, 1075
        - ureteral stent, 1071
        - ureteropelvic junction disruption, 1074–1075, 1075*f*
        - ureteropelvic junction obstruction, 1076, 1076*f*
    - penile, 1083–1084, 1083*t*
    - persistent or delayed bleeding of, 1072–1073
    - scrotal, 1084, 1084*t*, 1085*f*
    - ureteral, 1078–1079, 1080*b*
        - American Association for Surgery of Trauma Classification, 1079, 1079*t*
        - distal ureteral injury surgical repair, 1079
        - epidemiology of, 1078
        - follow-up imaging, 1079
        - imaging findings of, 1079
        - lengthy ureteral injuries, 1079
        - management of, 1079
        - presentation of, 1078–1079
        - proximal or mid-ureteral injury surgical repair, 1079
    - urethral, 1081–1083, 1081*t*, 1083*b*
        - evaluation of, 1081
        - in females, 1083
        - management of, 1081–1083, 1082*f*
    - vaginal, 1084–1086, 1085*t*
- Pediatric kidney stone disease

conservative management of, 865*b*

evaluation of, 854–856, 859*b*

extrarenal manifestations of, 853–859, 854*b*

goals of therapy for, 860–861

laparoscopic and robotic-assisted pyelolithotomy for, 868–870

management of, 853–870, 854*f*

medical expulsion therapy for, 859–860

medical history in, 856–857

medications for, 869–870

metabolic investigations in, 856–857, 857*t*

percutaneous nephrolithotomy, 865–868, 866*t*, 868*b*

- complications, 868
- planning for, 867
- technique for, 867–868, 867*f*–868*f*

physical examination for, 856–857

secondary prevention for, 868–869

shock wave lithotripsy for, 864–865, 865*b*

- limitations and concerns with, 865
- stone size, location, and composition, 864–865
- technique for, 865

surgical management of, 860, 860*t*

ureteroscopic management of, 861–863, 864*b*

- equipment for, 863, 863*f*
- indications for, 861, 862*t*
- limitations and complications of, 864
- technique for, 863–864, 863*f*

urinary metabolic abnormalities of, 857–858

- cystinuria, 859
- hypercalciuria, 857–858, 858*t*
- hyperoxaluria, 858, 858*t*
- hyperuricosuria, 858*t*, 859
- hypocitraturia, 858–859
- primary hyperoxaluria, 858
- secondary hyperoxaluria, 858–859

Pediatric nephrology, urologic aspects of, 341–357

    - radiographic imaging, 2536
    - ultrasonography, 2536
    - urinalysis, 2534
    - urodynamics, 2534–2536, 2536*b*
    - voiding diaries for, 2530

  symptom quantification instruments for, 2531
  terminology of, 2526*t*

Pelvic floor muscle (PFM)
  assessment of, for PFMT, 2723–2725
  contraction of, to prevent stress incontinence, 2540, 2725
  dysfunction of, behavioral training for, 2732–2735
  electrical stimulation of, 2729–2730
  female, 2430–2432, 2432*f*
  for SUI, 2540
  teaching control of, 2725

Pelvic floor muscle exercise (PFME), for urinary incontinence, in geriatric patients, 2919.e2

Pelvic floor muscle training (PFMT), 2723–2727
  assessment of PFMF, 2723–2725
  biofeedback for, 2729, 2729*f*, 2729.e1*f*–2729.e2*f*
  evidence for, 2725–2726
  exercise regimens for, 2725, 2725.e1*t*
  handout for, 2725.e1*t*
  levels of evidence and recommendations for, 2722.e1*b*–2722.e4*b*
  as nonsurgical treatment option, 2833
  for prevention of stress incontinence, 2725
  teaching of, 2725
  vaginal cones for, 2726, 2726.e1*f*

Pelvic floor physiotherapy
  for chronic scrotal pain syndrome, 1221
  for detrusor underactivity, 2660

Pelvic fracture, bladder injuries with, 3057

Pelvic fracture urethral injuries (PFUIs), 1828–1834
  evaluation of, 1829
  postoperative management of, 1832–1834, 1834*f*
  repair of, 1829–1832, 1830*f*–1833*f*

Pelvic inlet, female, 2427, 2428*f*

Pelvic lymphadenectomy (PLND)
  extended
    common iliac, 3152, 3153*f*–3154*f*
    external iliac, 3148–3149, 3151*f*
    hypogastric, 3149–3152, 3153*f*
    obturator, 3149, 3152*f*
    presacral, 3152, 3154*f*
  in laparoscopic radical prostatectomy, 3577
  for penile cancer, 1761–1762
  for prostate cancer staging, 3521
  radical cystectomy with
    anatomic extent of, 3115–3116
    bilateral, 3115
    density of, 3117
    distal urethra management, 3118
    extracapsular nodal extension, 3117
    intraoperative decision making, 3117–3118
    intraoperative frozen sections of ureter, 3117–3118
    managing female urethra in, 3118
    for muscle-invasive bladder cancer, 3114–3119
    number of lymph nodes identified, 3116–3117, 3116*f*
    oncologic outcomes following, 3118–3119, 3118*t*
    prostatic urothelial carcinoma and, 3118
  with transurethral resection of bladder tumor, 3137–3138, 3138*f*–3139*f*
Pelvic muscle electromyography (EMG), 2557
Pelvic muscle training device, 2727*f*
Pelvic nerve afferents, 2481–2482, 2481*t*, 2482*f*
Pelvic node dissection, in robotic prostatectomy, 3580–3581
Pelvic organ cross-sensitization, in BPS/IC etiology, 1232.e9, 1232.e9*b*
Pelvic organ prolapse (POP), Pelvic floor disorders
  classification of, 2526, 2527*f*, 2587–2589, 2589*b*
    systems for, 2529–2530, 2529*f*, 2530*t*
  conditions associated with, 2592*b*
  consequences of, 2592–2593, 2592*b*
  definition of, 2587–2589, 2589*b*
  epidemiology of, 2590–2591, 2591*b*
  female sexual dysfunction and, 1656–1657

- financial impact of, 2593

  - curative purposes, surgery for, 1796
  - palliative purposes, surgery for, 1800
  - radical inguinal lymph node dissection, 1796–1798, 1799*f*–1800*f*
- radiation therapy for, 1765–1769, 1769*b*
  - adverse effects of, 1767–1768
  - inguinal areas, 1768–1769, 1769*f*
  - primary lesion, 1765–1768
- risk-based management of inguinal region in, 1762–1765, 1763*f*–1764*f*
  - bulky adenopathy and fixed nodal metastasis, 1765
  - high-risk patients, 1762–1765
  - low- to intermediate-risk patients, 1762

- very low-risk patients, 1762
- surgical management of, 1753*t*, 1753*b*, 1792
  - amputation, 1752–1753

Penile elephantiasis, as filariasis clinical manifestation, 1330

Penile erection, 1485–1512, Erectile dysfunction

- physiology of, 1485–1500, 1490*b*, 1495*b*
  - functional anatomy of, 1485–1487, 1486*f*–1488*f*, 1486*t*
  - hemodynamics and mechanism of erection and detumescence, 1487–1489, 1489*f*, 1490*t*
  - historical context of, 1485
  - neuroanatomy and neurophysiology of, 1489–1495, 1490*f*, 1491*t*–1492*t*
  - smooth muscle, 1495–1500, 1496*f*–1497*f*, 1500*b*, 1501*f*

Penile imaging, in priapism, 1549–1550, 1550*f*, 1550*b*

Penile incisions, in urologic surgery, 143–144, 143*f*

Penile magnetic resonance imaging, 1524

Penile near infrared spectrophotometry, 1524–1525

Penile pain, patient history of, 2

Penile plethysmography, 1524

Penile prosthesis

- for Peyronie's disease
  - indications for, 1624
  - techniques for, 1624–1625, 1625*t*
- surgery, 1537

Penile rehabilitation, role of, in laparoscopic radical prostatectomy, 3579

Penile revascularization surgery, 1537

Penile thermal sensory testing, 1527

Penile torsion, 394

Penile traction, and PD, 1614–1615, 1617*t*

Penile transplantation, 1838–1842, 1840*f*, 1842*b*

- after trauma, 1841

Penile tumescence and rigidity monitoring, 1525–1526, 1525*f*

Penile urethra, 1383, 1383*f*, 1807.e4*f*, 1807.e8

- carcinoma of, 1780–1781, 1781*f*

Peninsular flaps, for urethral and penile reconstruction, 1807

Penis

- amputation of
  - for penile cancer, 1752–1753
  - traumatic, 3050–3051
- anatomy of, 1387*b*, 1485–1487, 1486*t*, 1807.e8–1807.e9, 1807.e10*b*
  - arterial supply, 1384–1385, 1386*f*, 1807.e5*f*
  - arteries, 1487, 1487*f*
  - blood supply, 1807.e8–1807.e9
  - corpora cavernosa, corpus spongiosum, and glans penis, 1485–1486
  - lymphatics, 1386, 1807.e9
  - nerve supply, 1386, 1387*f*, 1807.e9
  - reconstructive surgery and, 1807, 1807.e1*f*–1807.e7*f*
  - sphincteric, 1807.e8
  - structure, 1383–1384, 1385*f*–1386*f*
  - urethral, 1807.e8
  - venous drainage, 1385, 1487, 1488*f*, 1807.e5*f*
- curvatures of, Curvatures of penis
- in genitourinary tuberculosis, 1309
- imaging of
  - cavernosogram, 1386, 1387*f*
  - Doppler ultrasound, 1386, 1387*f*
  - magnetic resonance imaging, 1386, 1388*f*
- injuries and trauma of, 3048–3051
  - amputation, 3050–3051
  - animal and human bites, 3050
  - burns, 3053
  - with circumcision, 874*f*, 875
  - fracture, 3048–3049, 3048.e1*f*, 3049*f*–3050*f*, 3049.e1*f*
  - gunshot wounds, 3049–3050
  - microvascular, 3050
  - penetrating, 3049–3051
  - strangulation, 3051
  - total reconstruction after, 1841
  - zipper, 3051
- length of, 871, 872*t*
- nerve supply of, 305–306
- neuroanatomy and neurophysiology of
  - neurotransmitters and, 1492–1495, 1495*t*
  - spinal centers and peripheral pathways, 1489–1491, 1490*f*, 1491*t*

  - supraspinal pathways and centers, 1491–1492, 1491*t*–1493*t*
- physical examination for, 10–11
- physiology of
  - corpora cavernosa, 1488–1489, 1489*f*
  - corpus spongiosum and glans penis, 1489, 1490*t*
- preservation of, in penile cancer management, 1751
- reattachment of, 3051*b*
- reconstructive surgery of, 1804–1842, 1805*b*, 1813*b*, 3054
  - for amyloidosis, 1810
  - anatomy of, 1807, 1807.e1*f*–1807.e7*f*
  - balanitis xerotica obliterans, 939, 940*f*
  - for balanitis xerotica obliterans, 939, 940*f*
  - for circumcision complications, 1811–1812
  - in classic bladder exstrophy, 551–552, 552*f*–553*f*
  - for curvatures of penis, 1836–1838, 1838*b*
  - for failed epispadias repair, 1813
  - for failed hypospadias repair, 1812–1813
  - for female-to-male transgender, 1841–1842, 1842*b*
  - for fistulae of posterior urethra, 1835–1836, 1836*b*
  - for glans dehiscence, 937, 938*f*
  - for LS, 1808–1810, 1809*f*
  - in male epispadias, 569
  - for meatal stenosis, 937–938, 1811
  - for paraphimosis, balanitis, and phimosis, 1811
  - penile transplantation, 1838–1842, 1840*f*, 1842*b*
  - for PFUIs, 1828–1834, 1830*f*–1834*f*
  - principles of, 1804–1807, 1806*f*–1807*f*, 1808*b*
  - for recurrent penile curvature, 939–941, 940*f*
  - for urethral diverticulum, 938–939, 939*f*, 1810–1811
  - for urethral stricture, 938, 1814–1828, 1814*f*, 1828*b*
  - for urethrocutaneous fistula, 935–937, 936*f*–937*f*, 1810
  - for vesicourethral distraction defects, 1834*b*, 1835, 1836*b*
- skin complications of, 874
- tumors of, 1742–1775
  - malignant, Penile cancer
  - premalignant cutaneous lesions, 1742
    - Buschke-Löwenstein tumor (giant condyloma acuminatum), 1742.e1*f*, 1742.e3
    - carcinoma in situ (penile intraepithelial neoplasia), 1742
    - non-human papillomavirus-related, 1742.e1–1742.e2
    - virus-related, 1742.e2–1742.e3, 1743*b*
  - squamous cell carcinoma, 1743–1751, Squamous cell carcinoma
  - surgical management of, 1751–1753, 1753*t*, 1753*b*
    - circumcision and limited excision strategies, 1752–1753
    - contemporary penile amputation, 1752–1753
    - laser ablation, 1752
    - Mohs micrographic surgery, 1752

organ preservation, 1751

ultrasonography of, 85–88, 86*f*

Penn pouch, 3224–3225, 3224*f*

Penoscrotal transposition, 886*f*

Penrose drains, 148

Pentosan polysulfate, for chronic scrotal pain syndrome, 1216

Pentoxifylline, for PD, 1611, 1616*t*

Peptide hormones, of reproductive axis, 1390, 1391*f*

Peptidergic agents, in ureteral function, 1889

PERC Mentor, 176, 177*f*

Percutaneous antegrade endopyelotomy, for ureteropelvic junction obstruction, 1947

complications with, 1949

indications and contraindications for, 1947, 1947*f*

patient preparation for, 1947

postoperative care for, 1948

results with, 1949

technique of, 1947–1948

Percutaneous drain, for pediatric genitourinary trauma, 1071–1072, 1072*f*

Percutaneous endopyeloplasty, for ureteropelvic junction obstruction, 1949

Percutaneous epididymal sperm aspiration, in sperm retrieval, 1474, 1474*f*

Percutaneous nephrolithotomy (PCNL), 243.e1, 2103–2107, 2105*b*

anesthesia for, 2104

antibiotics for, 2104

calyceal diverticula and, 2105, 2105*f*

clinical use of, 246

complications of, 2107

CyberWand, 245

horseshoe kidney and, 2105–2106

laser fragmentation, 244.e3

morbid obesity and, 2089, 2106–2107

- old age and frailty and, 2089–2090
- patient preparation, 2103–2104
- pediatric, 865–868, 866*t*, 868*b*
    - complications, 868
    - planning for, 867
    - technique for, 867–868, 867*f*–868*f*
- prior renal surgery and, 2090
- for renal calculi
    - in calyceal diverticula, 2078
    - in horseshoe kidneys, 2080
    - lower pole calculi, 2081, 2081*f*, 2082*t*, 2083*f*
    - in renal ectopia, 2080, 2081*f*
    - stone composition and, 2076, 2076*f*
    - stone localization and, 2075
- renal function and, 2088–2089
- renal transplants and, 2091
- ShockPulse-SE, 245–246
- solitary kidney and, 2089
- spinal deformity or limb contractures and, 2090
- for staghorn calculi, 2074
- staghorn calculi or complex stones and, 2106
- stone burden and
    - between 1 and 2 cm, 2073
    - greater than 2 cm, 2074
    - up to 1 cm, 2072–2073
- stone removal in, 2104–2105
- tissue effects, 246
- transplantation and pelvic kidneys and, 2106, 2106*f*
- uncorrected coagulopathy and, 2090
- for ureteral calculi
    - duplicated collecting system and, 2087
    - in megaureter, 2087
    - outcome of, 2091–2093
    - stone composition and, 2087
    - stone localization and, 2085–2086, 2086*t*
- urinary diversion and, 2091
- urinary tract infection and, 2088

Percutaneous nephrostomy drains, 288

Percutaneous nerve evaluation test, for sacral neuromodulation, 2754

Percutaneous posterior tibial nerve stimulation (PTNS), for UUI, 2546

Percutaneous procedures, antimicrobial prophylaxis for, 1199

Percutaneous pyelolithotomy, 160

Percutaneous renal access and drainage, 160–182

- anatomic considerations of, 160–164
  - collecting system, 161–162, 162*f*
  - intrarenal vasculature, 162–164, 163*f*
  - perirenal anatomy, 160–161, 161*f*
  - renal parenchyma, 161–162
- anesthetic considerations for, 165
- complications, 178–182, 182*b*
  - acute hemorrhage, 178
  - death, 182
  - delayed hemorrhage, 178–179
  - fever and sepsis, 181
  - loss of renal function, 182
  - metabolic and physiologic, 181
  - neuromusculoskeletal, 181–182
  - pleural injury, 180–181
  - venous thromboembolism, 182
  - visceral injury, 179–180
- history of, 160
- image guidance for puncture, 166–169
- indications of, 160
  - diagnostic studies, 160
  - percutaneous renal surgery, 160
  - simple drainage, 160
  - therapeutic instillations, 160
- obtaining, 169*b*
- postprocedural drainage, 173–176
  - general considerations of, 174–175
- special situations, 177–178
  - horseshoe kidney, 177
- surgical technique, 164–176
  - advanced guidance techniques, 169–172
  - antimicrobial prophylaxis, 164
  - choice of calyx for access, 165
  - diagnostic imaging, 164

        - interpolar calyx, 166
        - lower pole calyx, 166
        - management of anticoagulation, 164
        - obtaining access, 164
        - patient positioning, 164
        - prone position, 164–165, 165*f*
        - supine position, 165
        - upper pole calyx, 165–166, 166*f*
    - training for, 176

Percutaneous renal tumor ablation, 2312, 2313*f*, 2318

Percutaneous Shunting in Lower Urinary Tract Obstruction (PLUTO) trial, 364

Percutaneous stone removal, 2069.e2

Percutaneous surgery, 243.e2

Percutaneous tibial nerve stimulation (PTNS), 2748–2751, 2749*f*
- clinical results of, 2749–2750
- compared with other treatments, 2750
- history of, 2749
- implantable, 2750–2751, 2751*f*
- prognostic factors for, 2750
- technique of, 2749, 2750*f*

Perforating artery, 136*f*

Perforation
- of bladder, in transurethral resection of bladder tumor, 3135*f*
- with monopolar transurethral resection of prostate, 3417
- ureteral, ureteroscopic, 2002
- in ureteroscopic stone management, 2108

Perfusion phase, 92–93

Perfusion studies, for UPJO, 1944–1945

Perinatal neuroblastoma, surgical treatment of, 1093

Perinatal testicular torsion, 897, 897*f*

Perinatal urology, 358–387
- congenital adrenal hyperplasia, 382, 383*f*
- exstrophy, 379–382

- grading systems, 358–361
- key conditions, 372–375
- kidney anomalies, 377–379
- lower urinary tract obstruction, 375–377, 376*f*–377*f*
- perinatal urgencies/emergencies, 382–387
- postnatal evaluation and management, 366–370, 367*b*, 370*b*
  - imaging, 367–370
  - magnetic resonance urography, 369–370
  - renal scintigraphy, 367–369, 369*f*–370*f*
  - renal ultrasound/resolution of urinary tract dilation, 367, 368*f*
  - voiding cystourethrogram, 367
- postnatal urinary tract dilation, management recommendations for, 370–372
- prenatal imaging, 358, 358*b*
- prenatal multidisciplinary consultations, 361–362, 362*b*
- urinary tract dilation, 362–366
- urogenital sinus, 382, 382*b*, 383*f*

Perineal body, 1807.e10, 2434
- fasciae of, 2449, 2450*f*–2451*f*
- female sexual organs, 1627.e2

Perineal bone-anchored slings, 2887

Perineal incisions, in urologic surgery, 144

Perineal membrane, 2434

Perineal pain, after transurethral needle ablation of prostate, 3433

Perineal ultrasonography, of penis and male urethra, 85, 87*f*

Perineal urethrostomy, for urethral stricture disease, 1827–1828

Perineorrhaphy, posterior colporrhaphy with, for pelvic organ prolapse repair, 2827–2829

Perinephric abscess
- after renal injury, 1992
- as renal infection, 1174–1176, 1175*f*

Perinephric fat, 1865

Perineum
- fasciae of, 2449, 2450*f*–2451*f*

- female, 2434–2435, 2435*f*
- Fournier gangrene and, 1289–1290, 1290*f*
- male, 2450*f*–2451*f*, 2451*b*
  - anatomy of, 1807.e9–1807.e10, 1807.e10*b*

Perineural invasion, 3512

Perioperative intravesical therapy, for non-muscle-invasive bladder cancer, 3098–3099

Peripheral benzodiazepine receptor (PBR), 1394–1395

Peripheral (or modified-peripheral) loading, 3596

Peripheral nervous system, of lower urinary tract, 2480–2497, 2480*f*

- afferent pathways in, 2481–2486, 2481*t*, 2482*f*–2486*f*, 2487*b*
- efferent pathways to, 2487–2493, 2487*f*, 2489*f*–2492*f*, 2490*b*, 2491*t*
- parasympathetic pathways, 2480, 2480*f*
- somatic pathways, 2480*f*–2481*f*, 2481
- supraspinal pathways, 2493–2497, 2495*f*–2496*f*
- sympathetic pathways, 2480, 2480*f*

Peripheral neuropathy, 146

Periprostatic plexus, 1380

Perirenal anatomy, 160–161, 161*f*

Peristalsis, of ureters

- cellular, 1877
- contractile activity, 1883–1887, 1883*f*–1886*f*
- development of, 1877–1878, 1878*f*
- drug effects on, 1901–1903
- electrical activity, 1878–1883, 1879*f*–1880*f*
- mechanical properties, 1890–1891, 1890*f*–1891*f*
- nervous system function in, 1887–1890
- urine transport, 1891–1894, 1892*f*–1893*f*

Peritoneal dialysis, in children, 356, 357*b*

Peritoneal flap, for vesicovaginal fistula repair, 2940, 2940*f*

Peritoneum

  - female, 2427, 2429*f*
  - male, 2448*f*, 2449

Peritubular tissue, 1398, 1398*f*

Periureteral fascia, 1865

Periurethral abscess, 1182, 1182*b*

Periurethral bulking agents
  - as alternative treatment for slings, 2833
  - for neuromuscular dysfunction of lower urinary tract, 637
  - urethral diverticula differentiated from, 2987

Periurethral glands, 2439
  - urethral diverticula and, 2976

Periurethral region, natural defenses of, 1137

Periurethral technique, injection, 2892

Perivascular epithelioid cell tumor, retroperitoneal tumors and, 2234

Permeability, of urothelium of bladder, 2461–2462, 2467, 2468*f*

Pernicious anemia, lower urinary tract dysfunction with, 2619

Persistent genital arousal disorder, 1636

Persistent Müllerian duct syndrome (PMDS), 322, 323*f*, 1016–1017, 1016*f*

Persistent penile erection, with monopolar transurethral resection of prostate, 3417

Pessaries
  - continence, 2736, 2736*f*, 2736.e1*f*
  - for pelvic organ prolapse, 2920.e9–2920.e10

PET, Positron emission tomography

Peyronie's disease (PD)
  - and aging, 1600
  - and collagen disorders, 1602
  - and combination therapy, 1615
  - curvatures of penis associated with, 1837–1838
  - and diabetes, 1600, 1601*f*

- diagnosis and management of, 1599–1626

PGI-I, Post-operative Patient Global Impression of Improvement

pH, of urine, 15–16
- low
    - in calcium stone formation, 2024–2025
    - in uric acid stone formation, 2027–2029, 2028*f*

Phallic urethra, 3068, 3069*f*

Phalloplasty, 3068

Pharmacologic therapy
- in ED, 1532–1536, 1533*b*, 1538*b*
    - future directions for, 1538
    - intracavernosal injection, 1534–1535, 1535*t*
    - intraurethral suppositories, 1535–1536
    - oral, 1532–1534
    - transdermal/topical, 1536
- to facilitate bladder emptying, 2716–2720
    - by bladder contractility, 2716–2718
    - by decreasing outlet resistance, 2719–2720, 2720*b*
    - by increasing intravesical pressure, 2716–2718
- to facilitate bladder filling and urine storage, 2679–2716, 2682*t*
    - α-adrenoreceptor antagonists, 2682*t*, 2697–2698
    - β-adrenoreceptor antagonists, 2682*t*, 2698–2699
    - antidepressants, 2682*t*, 2702–2703
    - antimuscarinic agents, 2681–2684, 2682*t*, 2697*b*, Antimuscarinic agents, to facilitate bladder filling and urine storage
    - in augmented or intestinal neobladders, 2712–2713
    - botulinum toxins, 2682*t*, 2707–2709
    - cannabinoids, 2713.e2–2713.e3
    - centrally acting drugs, 2713.e3–2713.e4
    - combinations for, 2704–2707

        - cyclooxygenase inhibitors, 2682*t*, 2703
        - desmopressin for, 2710–2712
        - dimethyl sulfoxide, 2703–2704
        - estrogens for, 2709–2710, 2713–2714
        - future possibilities of, 2713
        - gabapentin, 2713.e3
        - gonadotropin-releasing hormone antagonists, 2713.e3
        - guidelines for, 2681*t*
        - by increasing outlet resistance, 2713–2716
        - by inhibiting bladder contractility, 2679–2700
        - intraprostatically injected drugs, 2713.e2–2713.e3
        - membrane channel activity, 2682*t*, 2696–2697
        - mirabegron, 2699–2700
        - muscarinic receptors in, 2679–2681, 2680*t*
        - NK_1-receptor antagonists, 2713.e4
        - phosphodiesterase inhibitors, 2682*t*, 2700–2702
        - prostanoid-receptor agonists and antagonists, 2713.e1–2713.e2
        - toxins, 2707–2709
        - tramadol, 2713.e3–2713.e4
        - transient receptor potential channel antagonists, 2713.e1
        - vanilloids for, 2709
        - vitamin D_3-receptor analogues, 2713.e1
    - for hypospadias, 945
    - for lower urinary tract, 2497–2503
        - adrenergic mechanisms, 2500–2501, 2501*f*, 2501*b*
        - afferent neuropeptides, 2501–2502, 2501*t*
        - muscarinic mechanisms, 2497–2500, 2499*t*, 2500*b*
        - sex steroids, 2502–2503
        - urethral tone in women, 2501
- Phenazopyridine, for pelvic floor disorder testing, 2533
- Phenotypic gender development, 1390
- Phenotypic sexual differentiation, 995–996, 995*f*–997*f*
- Phenoxybenzamine
    - to facilitate bladder emptying, 2720.e1
    - ureteral response to, 1888
- Phentolamine (Regitine), 1535
    - ureteral response to, 1888
- Phenylephrine
    - in priapism, 1551

  - ureteral response to, 1888

Phenylpropanolamine (PPA), for stress urinary incontinence in women, 2714

Pheochromocytoma, 451–452
  - clinical characteristics, 2373–2375, 2375*t*
  - contrast media and, 32
  - diagnostic tests, 2375–2378, 2376*f*–2378*f*, 2377*t*, 2402, 2402*t*
  - hereditary, 2373, 2374*t*, 2375, 2380
  - increased adrenal function in, 2373–2380, 2373*f*, 2374*t*–2375*t*, 2376*f*–2379*f*, 2377*t*
  - malignant, 2373, 2375, 2380
  - MRI and, 54
  - overview and epidemiology, 2373, 2373*f*
  - pathophysiology, 2373
  - prognosis, 2380
  - surgery, 2409, 2409*b*
  - treatment, 2378, 2379*f*, 2409, 2409*b*

Phimosis, 393, 871–872, 872*f*
  - urethral reconstructive surgery for, 1811

Phosphate
  - in crystal formation, 2014
  - transport of, urinary tract obstruction and, 794

Phosphatidylinositol 3-kinase (PI3K) pathway, in prostate cancer, 3469

Phosphaturia, in urine, 14

Phosphodiesterase
  - in ED, 1498–1499
  - for PE, 1572

Phosphodiesterase inhibitors
  - for BPS/IC oral therapy, 1243
  - to facilitate bladder filling and urine storage, 2682*t*, 2700–2702

Phosphodiesterase type 5 inhibitors (PDE5-I)
  - for benign prostatic hyperplasia, 3382, 3393, 3394*t*
  - for chronic scrotal pain syndrome, 1216
  - for ED, 1532–1534, 1532*t*

- for female orgasmic disorder, 1648
- for female sexual arousal disorders, 1650
- for PD, 1611–1612
- for priapism, 1554
- rationale and efficacy of, 3382–3385, 3382*f*, 3383*t*–3384*t*, 3385*f*

Phosphorus, metabolism of, 2016

Phosphorylcholine, in prostatic secretions, 3296

Photodynamic therapy (PDT), for refractory high-grade non-muscle-invasive bladder cancer, 3106

Photon, 238

Photoselective vaporization of prostate (PVP), 3438–3442
- in anticoagulated patients, 3441
- complications with, 3441–3442
  - intraoperative, 3441
  - perioperative, 3441
  - postoperative, 3441–3442
- concept and introduction for, 3438–3439
- conclusion for, 3442
- outcomes with, 3440–3441
  - comparative studies, 3440–3441
  - single-cohort studies, 3440
- technique for, 3439–3440
  - intraoperative, 3439
  - postoperative, 3439–3440
  - preoperative, 3439

Phototherapy, for chronic scrotal pain syndrome, 1216

Physical activity, benign prostatic hyperplasia and, 3324, 3325*t*

Physical examination, 1434–1436, 1436*b*
- bladder, 10, 10*f*–11*f*
- of male reproductive system, 1435–1436
  - phallus, examination of, 1436
  - prostate and seminal vesicles, 1436
  - scrotum, examination of, 1435
  - spermatic cord, examination of, 1435–1436
  - testis and epididymis, examination of, 1435, 1435*f*

  - penis, 10–11
  - scrotum, 11, 11*f*
  - in urinalysis, 14

Physiologic hydronephrosis, of pregnancy, 284

Physostigmine, ureteral response to, 1887–1888

Phytotherapy

  - for benign prostatic hyperplasia, 3393–3399
  - current role of, 3395
  - extract composition of, 3394, 3394*t*–3395*t*
  - mechanism of action, 3394–3395, 3395*t*
  - origin of agents for, 3394, 3394*t*

PI3K/Akt/mTOR pathway, in castration-resistant prostate cancer, 3699–3700

PIA, Proliferative inflammatory atrophy

Piezoelectric generator, 2094, 2096*f*

Pigment-related kidney injury, 1924

Pigtail drains, 148

Pili, 428–429

  - bacterial type 1 (mannose-sensitive), 1134
  - classification of, 429
  - P (mannose-resistant), 1134–1135

PIN, Prostatic intraepithelial neoplasia

Pioglitazone, bladder cancer and, 3077

Pippi Salle procedure, for bladder neck reconstruction, 690, 691*f*

PIRADS, Prostate Image Reporting and Data System

Pituitary tumors, 1448

Pivmecillinam, for UTIs, 1155–1156

PIVOT, 3530–3531

Placenta accreta, 294, 303

Placental abnormality, urologic management of, 294–295, 295*b*

Plain abdominal radiography, 35–36, 36*f*–37*f*, 415

Planning target volume (PTV), 3590

Plaques, of urothelium of bladder, 2462

Plasma creatinine (PCr), GFR estimation with, 1905, 1906*f*

Plasma free metanephrines, in evaluation of adrenal masses, 2402, 2402*t*

Plasma markers, GFR estimation with, 1905, 1906*f*

Plasmacytoma, retroperitoneal tumors and, 2236

Plateau-shaped curve, 480

Platelet transfusion, 147

Platinum agents, 3693

Pleomorphic liposarcoma, retroperitoneal tumors and, 2230–2231

PLESS, Proscar Long-Term Efficacy and Safety Study

PLISSIT Model, for female sexual function, 1628–1629, 1628*t*–1629*t*

PLND, Pelvic lymphadenectomy

Ploidy-flow cytometry, in UTUC, 2198

PNET, Primitive neuroectodermal tumor

Pneumatic compression stockings, VTE prophylaxis with, for laparoscopic and robotic surgery, 231

Pneumatic lithotripsy, 243, 243*b*

- basic physics, 243
- tissue effects of, 243

Pneumaturia, patient history of, 7

Pneumomediastinum, during laparoscopic and robotic surgery, 225

Pneumopericardium, during laparoscopic and robotic surgery, 225

Pneumoperitoneum

- for laparoscopic and robotic surgery
  - acid-base metabolic effects of, 222
  - cardiovascular effects of, 220–221
  - complications related to, 224

        - mesenteric blood flow and intestinal motility effects of, 222
        - pressure of, 220
        - renal effects of, 221
        - respiratory effects of, 221
    - physiology of, 460–461, 462*b*
    - stress response to, 461
- Pneumothorax, during laparoscopic and robotic surgery, 225
- Podophyllin, for condylomata acuminata, 1742.e3
- Poiseuille's law, 932, 935*f*
- Polaris Loop stent, 176*f*
- Pole calyx
    - lower, 166, 166.e1*f*
    - upper, 165–166, 166*f*, 166.e1*f*
- Poliomyelitis, lower urinary tract dysfunction with, 2619
- Politano-Leadbetter technique, for vesicoureteral reflux in children, 837*f*–839*f*, 840
- Political support, in transitional urology, 1045
- Pollakiuria, 660
- Poly-ADP-ribose polymerase (PARP) inhibitors, 3702
- Polyamide (Nylon), 150
- Polyamines, in prostatic secretions, 3296
- Polyanion macromolecules, in crystal formation, 2014
- Polycythemia, in RCC, 2156
- Polydioxanone suture, 150
- Polyductin, 748
- Polyester (Mersilene), 150
- Polyglactin 910 suture, 149–150
- Polyglactin mesh, for anterior compartment repair, 2781*t*–2782*t*
- Polyglyconate (Maxon) suture, 150

Polyorchidism, 963

Polypharmacy, 2915–2917

Polypropylene (Prolene), 150

Polypropylene mesh, for pelvic organ prolapse reconstructive surgery, 2781*t*–2782*t*, 2783–2786, 2786*f*

Polyuria
- etiology of, 2678
- management of, 2678
- nocturia and, 2667, 2668*t*, 2678
- transient urinary incontinence and, 2919.e1

Pontine micturition center, 2493–2494, 2495*f*

Pontine tegmentum, 2493

POPQ, Pelvic Organ Prolapse Quantification

Population trends, aging and, 2906–2907

Porcine dermis, anterior repair with, for pelvic organ prolapse reconstructive surgery, 2781*t*–2782*t*, 2786–2787, 2787*f*

Porcine origin, of xenograft sling material, 2835

Port removal, after laparoscopic and robotic surgery, 218–219

Port site closure, after laparoscopic and robotic surgery, 219

Portal vein, 1673–1674, 1673*f*

Port-site hernias, 468–469

Port-site recurrence, of renal malignancy, 2297

Positional complication, in urologic surgery, 261–262

Positional nerve injury, in urologic surgery, 261–262

Positioning, Patient positioning

Position-related neuropathy, 146

Positive upper tract urinary cytology, 2219–2222, 2219*f*

Positron emission tomography (PET), 42

- for biochemical recurrence after radical prostatectomy, 3662, 3662*f*
- degree of radiotracer of, 91
- degree of visual conspicuity of, 91
- for inguinal node dissection, 1792
- physical characteristics of, 92*t*
- principles of, 91
- for prostate cancer, 3622
- radionuclides in, 91

Positron emission tomography magnetic resonance imaging, 44, 45*t*

Postchemotherapy retroperitoneal lymph node dissection (PC-RPLND), 2241
- adjuvant chemotherapy at, 1727
- auxiliary procedures for, 1717–1720, 1721*b*
  - hepatic resection, 1719–1720
  - major vascular reconstruction, 1718–1719, 1719*f*
  - nephrectomy, 1718, 1718*t*
  - pelvic resection, 1720
  - supradiaphragmatic disease, management of, 1720
- clinical complete remission to induction chemotherapy, 1721–1722, 1722*t*
- in high-risk populations
  - desperation RPLND, 1728, 1728*t*
  - late relapse RPLND, 1728*t*, 1729
  - reoperative RPLND, 1728*t*, 1729
  - salvage RPLND, 1727–1728, 1728*t*
- histologic findings at, survival outcomes and, 1726–1727, 1727*t*, 1727*b*

Post-chemotherapy surgery (PCS)
- for NSGCTs, 1698–1700, 1698*t*–1699*t*
- for seminomas, 1705–1706

Postcoital syndrome, 1636

Postcontrast acute kidney injury, contrast media and, 32–33

Posterior colpoperineorrhaphy, 2825

Posterior colporrhaphy, for pelvic organ prolapse repair, 2825–2829, 2825*f*
- perineorrhaphy, technique for, 2827–2829
- results with, 2827–2829, 2828*t*
- site specific, 2826–2827, 2826*f*–2827*f*

Posterior compartment prolapse, 2587

Posterior labial commissure, 1627.e1

Posterior lumbodorsal approach, to open adrenalectomy, 2411–2412, 2411*f*–2412*f*

Posterior lumbosacral incision, in urologic surgery, 141–142, 141*f*–142*f*

Posterior lumbotomy, for ureteropelvic junction obstruction in children, 829, 832*f*

Posterior pararenal space, 1666–1667, 1667*f*

Posterior pedicle dissection, ureteral control and, 3152–3157, 3155*f*–3156*f*

Posterior urethral valves, 375, 377*f*, 1053, 1053*b*

- sexual function and fertility, 1053

Posterolateral and multiple congenital diverticula, 522, 523*f*

Postexposure prophylaxis, for HIV treatment, 1264–1265

Posthysterectomy vesicovaginal fistulae, 2926–2927

Postmicturition leakage or dribble, 2540

- treatment of, 2547

Postnatal detection, incidental, of ureteral anomalies, 801

Postobstructive diuresis, 796

Postoperative care

- for laparoscopic simple nephrectomy, 2289
- for RPLND, 1717

Postoperative complications, adrenal surgery, 2424, 2424*b*

Postoperative management, for pheochromocytoma, 2380

Post-operative Patient Global Impression of Improvement (PGI-I), 2531

Postoperative urinary retention, lower urinary tract dysfunction and, 2629–2630

Postorgasmic illness syndrome (POIS), 1564, 1581, 1581.e1*b*, 1636

Postpartum, urinary incontinence and, PFMT for, 2726

Post-prostatectomy, vesicourethral region, 2993

Postprostatectomy incontinence (PPI), 2596

- PFMT for, 2726

Postrenal kidney injury, 1923

Post-SSRI sexual dysfunction, 1580

Post-translational modifications, of androgen, 3291

Post-void dribbling, for transmen, 3072

Postvoid residual (PVR), 482

- measurement in urinary incontinence, in men, 2543
- pelvic floor disorders and, 2534
- for sling procedure, 2832
- urinary flow rate with, 2565
- in urinary incontinence, in geriatric patients, 2920.e1
- in urodynamic studies, 2556

Postvoid residual volume, in benign prostatic hyperplasia, 3346

Potaba, for PD, 1610, 1616*t*

Potassium

- filtrate transport, 1909–1910, 1910*b*
- in kidney, of neonate, 342, 342*b*
- transport of, urinary tract obstruction and, 794

Potassium channel openers

- to facilitate bladder filling and urine storage, 2682*t*, 2697
- urethral function effects of, 1903

Potassium channels, in detrusor muscle, 2474, 2474*f*

Potassium chloride test, for BPS/IC diagnosis, 1238–1239

Potassium titanyl phosphate (KTP) laser, 239

Pouch calculi, with intestinal anastomoses, 3180*t*

Pouch of Douglas, 2427–2428

Power Doppler ultrasonography, 74

- transrectal, for prostate biopsy, 3500–3501, 3500*f*–3502*f*

PPNAD, Primary pigmented nodular adrenocortical disease

Practice accreditation, for ultrasonography, 89–90

Prazosin

- to facilitate bladder filling and urine storage, 2682*t*, 2720.e1
- ureteral response to, 1888

Precalyceal canalicular ectasia, 771

Precipitancy, 2919.e2

PRECISION trial, 3503–3504

Precoital pseudoephedrine, for delayed ejaculation, 1579

Precursor malignant lesions, of bladder, 3082–3083, 3083*f*

Pre-exposure prophylaxis, for HIV, 1265

Pregnancy
- augmentation cystoplasty and, 701
- bacteriuria in, 1184–1185, 1188*b*
  - anatomic and physiologic changes and, 1185–1186, 1185*t*, 1186*f*
  - complications of, 1186–1187
  - management of, 1186–1187, 1187*t*
  - pathogenesis, 1185
  - renal insufficiency and, 1187.e1
- classic bladder exstrophy, 290–291
- with congenital urologic conditions, 288–291, 291*b*
  - fertility, 288
  - mode of delivery, 289–290
  - myelomeningocele, 288–290
- considerations for imaging in, 284–285
- functional and anatomic urologic concerns during, 291–292
  - continent catheterizable stoma, 292
  - intermittent catheterization, 291
  - urinary diversion, 291–292
  - urinary tract infection and urinary diversion, 292
- genitourinary tuberculosis management during, 1318
- host defense mechanisms in UTIs and, 1140
- as laparoscopic and robotic surgery contraindication, 204
- neural tube defects, prevention of, 290
- PFMT during, 2726
- physiologic changes during, 282–284
  - cardiovascular, 282
  - hematologic, 282–283
  - hematuria, 283–284
  - renal and urinary tract, 283
  - respiratory, 282
  - urine chemistries during, 283
- physiologic hydronephrosis of, 284
- reflux and, 510–511, 511*b*
- renal calculi in, 2035
- RMS treatment effects on, 1116–1117
- surgical management of, 285
- ureter physiology effects of, 1900–1901
- urinary incontinence and, 2583
  - conservative interventions for, 2735

  - urinary tract infections in, management of, 293–294
  - urolithiasis in, 286–288, 288*b*
  - urologic considerations in, 282–295
  - urologic malignancy during, 292–293
  - urologic medication administration during, 285–286
  - in urologic surgery, 122
  - Wilms tumor treatment effects on, 1108

- Premature ejaculation, 1564–1572, 1572*b*
  - and assessment of erectile function, 1570
  - causes of, 1568–1569
    - acquired premature ejaculation, 1568
    - comorbid erectile dysfunction, 1568
    - hyperthyroidism and, 1568–1569
    - lifelong premature ejaculation, 1568
    - prostate disease, 1568
    - sexual performance anxiety, psychological or relationship problems and, 1568
  - classification of, 1564–1565
  - definition of, 1565–1567, 1565.e1, 1566*t*
  - and determination of intravaginal ejaculation latency time, 1569
  - diagnosis of, 1569
  - evaluation of, 1569
    - medical history in, 1569, 1569*t*
  - patient history of, 6
  - patient-reported outcome measures, 1569–1570
    - index of premature ejaculation, 1570.e1
    - premature ejaculation diagnostic tool, 1570.e1
    - premature ejaculation profile, 1570.e1
  - physical examination of, 1570, 1570*f*
  - prevalence of, 1567–1568, 1567*f*
  - treatment of, 1570–1572
    - pharmacologic, 1571–1572, 1573*t*
    - psychosexual therapy, 1571
- Prematurity, from bacteriuria in pregnancy, 1186
- Prenatal detection, of ureteral anomalies, 801
- Prenatal hydronephrosis, 401
- Prenatal imaging, and perinatal urology, 358, 358*b*

Prenatal mortality, from bacteriuria in pregnancy, 1186

Prenatal multidisciplinary consultations, 361–362, 362*b*

Prenatal ultrasonography, for pediatric urology, 389

Prenatal urinary tract dilation, etiology of, 372, 372*t*

Preoperative cardiovascular evaluation, 119–120

- clinical markers, 120
- functional capacity, 120
- surgery-specific cardiac risk, 120

Preoperative care

- for adrenal surgery, 2409–2410, 2409*b*
- evaluation
  - for kidney surgery, 2248, 2248.e1*f*, 2249*f*
  - for laparoscopic kidney surgery, 2279
- for laparoscopic and robotic surgery
  - blood products, 204
  - bowel preparation, 204
  - operating room setup, 205, 205*b*
  - patient positioning, 205, 205*f*
  - patient selection and contraindications, 203–204
  - prophylaxis, 205
- for minimally invasive urinary diversion, 3259, 3259*b*
- preparation for surgery
  - for kidney surgery, 2248, 2248.e1*f*, 2249*f*
  - for laparoscopic kidney surgery, 2279

Preoperative evaluation, 119

Preoperative management, for pheochromocytoma, 2378–2380

Preoperative multiparametric magnetic resonance imaging, use of, 3567

Preputial calculi, 2118–2119

Prerenal kidney injury, 353–354, 1922–1923

Presacral lymphadenectomy, 3152, 3154*f*

Prespermatogonia, 951

Pressure effects, for laparoscopic and robotic surgery, 221*t*

Pressure transmission theory, 2597*b*

Pressure ulcers, 2915

Pressure-flow study

- for benign prostatic hyperplasia, 3347
- in urodynamic studies, 2557

Presurgical testing, 119

- American Society of Anesthesiologists Classification and Risk, 119, 120*t*, 120*b*

Preureteral iliac artery, 824

Preureteral vena cava, 822–824, 823*f*, 824*b*

PREVAIL study, 3696

Prevesical space, 2427, 2429*f*, 2850

PRF, Retroperitoneal fibrosis

Priapism, 394–395, 885, 885*b*, 1539–1563

- causes of, 1542*b*
- classifying, 1539
- definition of, 1539, 1540*b*
- epidemiology and pathophysiology
  - in children, 1546
  - etiology of ischemic priapism (veno- occlusive, low-flow), 1541–1545, 1543*f*
  - etiology of nonischemic (arterial, high- flow), 1546, 1546*b*
  - etiology of stuttering (intermittent), 1545–1546, 1545*b*
- epidemiology of, 1540–1546
- evaluation and diagnosis of, 1547–1550
  - history of, 1547, 1548*f*, 1548*b*
  - laboratory testing in, 1548–1549, 1549*f*, 1549*t*
  - penile imaging in, 1549–1550, 1550*f*, 1550*b*
  - physical examination for, 1548, 1549*t*
- historical perspectives of, 1539–1540
- interventional angiography, 1560–1561, 1561*f*
- ischemic, 1539, 1540*f*
  - penile implants in, 1596
- medical treatments for, 1550–1554, 1552*b*, 1554*b*
  - ischemic priapism, 1550–1552, 1551*f*, 1552*b*
  - stuttering, 1553–1554

    - molecular basis of, 1547
    - nonischemic priapism, 1539, 1541*f*
    - sickle cell disease and, 1544, 1547*b*
    - stuttering priapism, 1539
    - surgical management of arterial, 1561, 1562*f*–1563*f*, 1562*b*
    - surgical management of ischemic, 1554–1560, 1558*b*
        - immediate implantation of penile prosthesis, 1558–1560, 1560*f*, 1560*b*
        - shunting, 1554–1558, 1555*f*–1559*f*, 1556*b*

- Primary aldosteronism
    - clinical characteristics, 2368
    - diagnostic tests, 2368–2372, 2369*b*–2370*b*, 2370*f*–2371*f*
    - increased adrenal function in, 2367–2372, 2367*f*–2368*f*, 2369*b*–2370*b*, 2370*f*–2371*f*, 2372*b*
    - overview and epidemiology, 2367
    - pathophysiology, 2367–2368, 2367*f*–2368*f*
    - treatment and prognosis, 2372, 2409*b*
- Primary ciliary dyskinesia, 1452
- Primary cutaneous lesions, 1273, 1274*t*
- Primary erectile dysfunction, causes of
    - micropenis, 1511
    - vascular abnormalities, 1511–1512
- Primary hyperoxaluria, 858, 2056–2057
    - medical therapy for, 2057
- Primary hyperoxalurias (PHs), 350, 2021–2022, 2021*f*
- Primary nephrotic syndrome, in children, 344
- Primary pigmented nodular adrenocortical disease (PPNAD), 2362
- Primary syphilis, 1255*t*, 1257, 1257*f*–1258*f*
- Primary urethral calculi, 2117
- Primary vestibulodynia, 1651
- Primitive neuroectodermal tumor (PNET), of kidney, 2181*t*, 2183
- Primordial germ cells, 318*f*
- Principal cells, epididymis, 1374–1375, 1403–1404

Pringle maneuver, in vena caval thrombectomy, 2273, 2273.e1*f*

Prior surgery, as laparoscopic and robotic surgery contraindication, 203

Probiotics, for UTIs, 1165

Processus vaginalis, 318–320

- cryptorchidism and, 962–963

Procidentia repair, 1051

Programmed cell death, Apoptosis

Programmed death-1 (PD-1), 2146

Progression, disease, 104–105

Progressive renal dysfunction, urinary tract obstruction and, 776, 777*f*

Projected isovolumetric pressure (PIP), 2658, 2658*f*

Prolactin, 1391, 1391*f*

- in benign prostatic hyperplasia, 3313
- in ED, 1494, 1495*t*

Prolapsed ureterocele, 395, 397*f*, 977, 978*f*

Prolaris test, 3488, 3521

Proliferative inflammatory atrophy (PIA), prostate cancer and, 3461

Promoters, of crystal formation, 2014–2015

Prompted voiding, 2730.e1*t*, 2731–2732

Prone position, 164–165, 165*f*

- modifications to, 165

Prone position for percutaneous nephroscopy, 146–147

Pronephros, 334–335, 334*f*

Propagation, electrical, in ureteral cells, 1882–1883

Propantheline bromide, to facilitate bladder filling and urine storage, 2682*t*, 2688

Prophylactic antibiotics, for UTI, 371–372

Prophylactic colposuspension, 2765

Prophylactic pelvic nodal treatment, for prostate cancer, 3602–3603, 3603*b*

Propiverine hydrochloride, to facilitate bladder filling and urine storage, 2682*t*, 2695–2696

- with α-adrenoreceptor antagonists, 2704

Propranolol (Inderal), ureteral response to, 1888

Proscar Long-Term Efficacy and Safety Study (PLESS), 3332, 3372–3373

PROSELICA trial, 3692–3693

Prospective European Doxazosin and Combination Therapy (PREDICT) study, 3385

PROSPER study, 3696

Prospermatogonia, 951

Prostaglandins (PGs)

- to facilitate bladder emptying, 2718–2719
- for female sexual arousal disorders, 1650
- in prostatic secretions, 3296
- urethral function effects of, 1902–1903
- urothelium release of, 2469–2470

Prostanoid-receptor agonists and antagonists, to facilitate bladder filling and urine storage, 2713.e1–2713.e2

Prostanoids

- for detrusor underactivity, 2661
- lower urinary tract and, 2502

Prostate

- anatomy of, 1381*b*
  - arterial supply, 1380, 1380*f*
  - gross structure, 1378–1379, 1379*f*
  - lymphatic drainage, 1380
  - microanatomic architecture, 1379–1380
  - nerve supply, 1380
  - ultrasonographic, 3490, 3491*f*–3492*f*
  - venous drainage, 1380
- cell types of, 3277*t*, 3278–3279, 3278*f*, 3279*b*
  - basal cells, 3278, 3278*f*

    epithelial stem cells, 3278*f*, 3279
    intermediate cells, 3278*f*, 3279
    luminal epithelial, 3278
    neuroendocrine cells, 3278*f*, 3279
development of, 311–317, 313*f*–316*f*, 315*t*, 317*t*, 317*b*, 3274–3280, 3277*t*, 3278*b*
    budding induction, 3274–3276
    budding of, 3274, 3275*f*
    cytodifferentiation, 3274
    epithelial budding, 3276
    fibroblast growth factors, 3276
    hedgehog signaling pathway, 3276
    molecular features of, 3274–3277
    Nkx3.1 and Sox9, 3276
    regional differentiation, 3274
    transforming growth factor-β superfamily, 3276–3277
    Wnt signaling pathway, 3276
    zonal and lobar anatomy, 3277, 3277*t*
endocrine control of growth of, 3280–3295, 3281*f*, 3284*b*
    adrenal androgens, 3282–3283, 3283*f*
    androgen production by testes, 3281–3282, 3282*f*–3283*f*, 3282*t*
    androgen-binding proteins in plasma, 3282*f*, 3284
    estrogens in male, 3282*t*, 3283–3284
fate of, in transwomen, 3063
in genitourinary tuberculosis, 1309
growth regulation of
    androgen action at cellular level, 3285–3286, 3285*f*
    androgen metabolism in, 3286–3287, 3286*f*, 3287*t*
    androgen receptor in, 3288–3292, 3289*f*–3290*f*
    androgen receptor-dependent chromatin remodeling, 3293–3295
    cell adhesion molecules, 3287–3288, 3288*b*
    at molecular level, 3288–3292
    protein growth factors in, 3284–3285, 3284*f*
    5α-reductase metabolism in, 3286–3287, 3286*f*, 3287*t*
    steroid receptors, 3288–3292
    steroids in, 3284–3285, 3284*f*
    stromal-epithelial interactions, 3287
localization studies, 1143
MRI of, T2-weighted, 1380–1381, 1381*f*
in prune-belly syndrome, 583–584, 584*f*
secretions of, Prostatic secretions
size of, benign prostatic hyperplasia and, 3320, 3320*f*, 3404
stents for, 3443–3444

- stroma of, 3280
- tissue matrix of, 3280
- transabdominal pelvic ultrasonography of, 80–81, 82*f*
- transrectal ultrasound of, 88–89, 89*f*, 1380, 1380*f*, 3493, 3493*f*, Transrectal ultrasonography, of prostate
- transurethral resection of, 1198–1199
- volume of
  - in acute urinary retention, 3338–3339, 3338*f*–3339*f*
  - transurethral microwave therapy and, 3426

Prostate adenocarcinoma, 3506–3512

- Gleason grading of, 3507–3509, 3508*f*, 3509*b*
- location of, 3507
- needle biopsy of, 3509–3510, 3510*b*
- radical prostatectomy specimens for, 3510–3512
- spread of, 3507
- staging classification for, 3506–3507
- subtypes of, 3512–3513
  - malignant tumors, 3513
  - mesenchymal, 3512
  - urothelial carcinoma, 3512–3513
- transurethral resection specimens for, 3510
- treatment effect and, 3512
- volume of, 3507

Prostate biopsy, 3494–3500, 3504*b*

- for adenocarcinoma, 3509–3510, 3510*b*
- advanced techniques for, 3500–3504
- after radiotherapy, for biochemical recurrence, 3666
- analgesia for, 3496–3497
- antibiotic prophylaxis for, 3496, 3496*t*
- bleeding with, 3499
- cleansing enema for, 3496
- complications of, 3499–3500
- contraindications to, 3495
- extended-core techniques, 3497, 3498*f*
- indications for, 3494–3495, 3495*b*
- infections after, 3499

- investigational techniques for, 3500–3504
- needle, 3519–3520
- patient positioning for, 3497
- patient preparation for, 3495–3497
- postradiation therapy, 3608
  - imaging and sampling error, 3609
  - interpretation of, 3608–3609, 3609*b*
  - timing of, 3608–3609
- PSA triggers for, 3516–3517
- repeat, 3497–3498
- risks of, 3499–3500
- saturation, 3497–3498
- sextant, 3497
- transperineal, 3498–3499
- transrectal techniques, 3497–3498
- transurethral, 3499

Prostate cancer, 1421–1422, 3063

- abiraterone for, 3677–3678, 3677*f*
- adenocarcinoma, Prostate adenocarcinoma
- African-Americans *versus* Caucasians, 3472, 3472*f*
- aminoglutethimide for, 3677
- androgen receptor in, 3472
- androgens, influence of, 3462, 3466, 3467*f*
- bicalutamide for, 3675
- biomarkers for, 3478–3489, 3489*b*, 3542–3543
  - annexin A3, 3487

Puberty, 1392

Pubic lice, Pediculosis pubis

Pubic rami, 2427

Pubic tubercles, 2428*f*

Public health notification, from USFDA Center for Devices and Radiological Health, 2777

Pubococcygeal line (PCL), 2537

Pubococcygeus muscle, 2430–2432, 2432*f*

Puboprostatic ligaments, division of, in retropubic radical prostatectomy, 3552, 3552*f*

Pubovaginal sling (PVS), 2833–2835

- allograft
    - materials for, 2834–2835
    - outcomes of, 2841–2843, 2841*t*–2842*t*
- anatomy for, 2834
- autologous graft
    - materials for, 2834
    - outcomes of, 2839–2841, 2840*t*
- complications of, 2848–2849, 2849*b*
    - nonurologic, 2849
    - perforation and exposure, 2848–2849
- evolution of, 2830
- materials for, 2834–2835, 2836*b*

- mechanics of, 2834
- operative procedure for, 2836–2839, 2839*b*
    - anesthesia for, 2836–2837
    - counseling, 2836
    - graft harvest for, 2837, 2837*f*
    - patient positioning for, 2836–2837
    - postoperative care for, 2839
    - preparation for, 2836–2837
    - sling placement and fixation in, 2838–2839, 2838*f*–2839*f*
    - vaginal dissection for, 2837–2838, 2838*f*
- outcomes of, 2839–2844, 2845*b*
    - for mixed urinary incontinence, 2844–2845
    - for urethral reconstruction, 2845
- retropubic suspension surgery *versus*, 2771–2773, 2772*f*
- synthetic prosthetic
    - materials for, 2835, 2836*t*
    - outcomes of, 2843
- voiding dysfunction after, 2845–2848, 2848*b*
    - surgical management of, 2846–2848, 2847*t*
- xenograft
    - materials for, 2835
    - outcomes of, 2843–2844, 2844*t*

Pubovesical ligaments, 2429–2430, 2438

Pudendal arteries, 1807.e4*f*
- preservation of, in retropubic radical prostatectomy, 3552, 3552*f*

Pudendal nerve, 2434
- stimulation of, 2511, 2751–2752
    - inhibitory and excitatory stimulation frequencies, 2511

Pulmonary abnormalities, with cloacal exstrophy, 575

Pulmonary complications
- after RPLND, 1730
- of radical nephrectomy, 2261–2266

Pulmonary embolism
- after laparoscopic and robotic surgery, 231
- after retropubic radical prostatectomy, 3563
- vena caval thrombectomy and, 2266–2267, 2277

Pulmonary evaluation, 120–121

Pulmonary hypoplasia, with posterior urethral valves, 610–611, 610*f*

Pulsed radiofrequency, for chronic scrotal pain syndrome, 1221

Pulsed wave lasers, 238

PUM, Partial urogenital mobilization

PUNLMP, Papillary urothelial neoplasm of low malignant potential

PUO, Partial ureteral obstruction

Purinergic nervous system, in ureteral function, 1889–1890

Purinergic signaling

- in bladder afferent pathway, 2484–2485, 2485*f*
- in bladder pain syndrome and interstitial cystitis, 2508

PVP, Photoselective vaporization of prostate

PVR, Postvoid residual

PVS, Pubovaginal sling

Pyeloenteric fistulae, 2953–2955, 2953*f*–2954*f*

Pyelogenic cyst, 774, 774*f*

Pyelography

- antegrade, Antegrade pyelography
- intravenous, Intravenous pyelography
- for pediatric genitourinary trauma, 1073–1074
- retrograde, Retrograde pyelography

Pyelolithotomy, laparoscopic pyeloplasty with, for ureteropelvic junction obstruction with, 1958–1960

Pyelolymphatic backflow, 38

Pyelonephritis, 398–400, 1129

- acute, 1168–1171, 1168*f*–1169*f*, 1170*t*
- chronic, 1176–1177, 1177*f*
- emphysematous, 1171–1172, 1171*f*
- with ureterointestinal anastomoses in urinary intestinal diversion, 3180*t*, 3192

  - XGP, 1177–1179, 1178*f*–1179*f*

Pyeloplasty, 836*b*
  - with concomitant pyelolithotomy, 1958–1960
  - dismembered, Dismembered pyeloplasty
  - laparoscopic, Laparoscopic pyeloplasty
  - laparoscopic dismembered tubularized flap, 1960
  - nondismembered, Nondismembered pyeloplasty
  - open surgery, 1953
  - for prune-belly syndrome, 592
  - results of, 1957–1958, 1959*t*
  - salvage procedures for, 1963

Pyelopyelostomy, for retrocaval ureter, 1963, 1965*f*

Pyelosinus backflow, 38

Pyelotubular backflow, 38

Pyeloureterostomy, for ureteral anomalies, 816–817, 817*b*

Pyelovascular fistulae, 2958

Pygeum africanum (African plum)
  - for benign prostatic hyperplasia, 3398
  - for nocturia, 2674

Pyoderma gangrenosum (PG), 1287–1288, 1288*f*

Pyonephrosis, 435
  - infected, 1174, 1174*f*

Pyridium, for pelvic floor disorder testing, 2533

Pyridoxine, for pediatric kidney stone disease, 870

Pyrophosphate, in crystal formation, 2014

Pyuria, 14, 426, 1129

Q

Qmax, 480–481, 481*t*

QOL-MED, 112*t*

Q-tip test, for urethral mobility, 2529

Quadratic fixation

- mechanisms of action of, 2995, 2995*f*
- mechanisms of continence of, 2995

Quadratus lumborum, 1658, 1662*f*–1665*f*, 1664*t*

Quadruple ureters, 821

Quality of care, definition of, 101

Quality of life, Health-related quality of life

- after androgen deprivation therapy, 3656
- after orthotopic urinary diversion, 3255–3257, 3256*t*, 3257*b*
- augmentation cystoplasty and, 702
- with cutaneous continent urinary diversion, 3226–3227
- cystinuria and, 2062–2063
- definition of, 116
- with exstrophy-epispadias complex, 567
- lower urinary tract dysfunction and, in pediatric patients, 652–653, 655*b*
- nocturia and, 2664
- with posterior urethral valves, 620, 623*b*
- in prune-belly syndrome, 595

Quality-of-life questionnaires

- for male urinary incontinence, 2541, 2541.e1*f*–2541.e2*f*, 2542*f*
- for pelvic floor disorders, 2531, 2532*t*–2533*t*

Quercetin, for BPS/IC oral therapy, 1241*t*, 1243

Questionnaire-Based Voiding Diary (QVD), 2723, 2723.e1*f*–2723.e2*f*

Quick flicks, 2730

Quiescent intracellular reservoir (QIR), 429

QVD, Questionnaire-Based Voiding Diary

R

RAA, Renal artery aneurysm

Race

- pelvic organ prolapse and, 2591
- urinary incontinence and, 2583–2585
- UTUC variations and, 2185

Race, prostate cancer and, 3457–3458, 3542

Rad, 28

Radiation

- for adrenal cortical carcinoma, 2387
- bladder cancer and, 3077
- in pediatric kidney stone disease, 861
- for retroperitoneal tumors, 2245

Radiation exposure, 28

- with CT, 780
- lower urinary tract dysfunction and, 2632
- medical diagnoses and, 2527

Radiation fistulae, 2959–2962

- chemotherapy of, 2961–2962

for seminomas, 1702–1703, 1703*t*
stereotactic body, 3593–3594
for TGCTs, 1692
in uroradiology, 28–29, 29*t*

        - radiation protection, 28–29
        - relative radiation levels, 28, 29*t*

Radiation Therapy Oncology Group (RTOG), 3594

Radical cystectomy
    - continence preservation in
        - anterior apical dissection in male patient, 3239–3240, 3241*b*
        - urethra preservation in female patient, 3240–3241, 3240*f*
    - history of, 3133
    - indications for, 3144
    - oncologic outcomes of, 3118–3119, 3133
    - with pelvic lymph node dissection
        - anatomic extent of, 3115–3116
        - bilateral, 3115
        - density of, 3117
        - distal urethra management, 3118
        - extracapsular nodal extension, 3117
        - intraoperative decision making, 3117–3118
        - intraoperative frozen sections of ureter, 3117–3118
        - managing female urethra in, 3118
        - for muscle-invasive bladder cancer, 3114–3119
        - number removed in, 3125
        - oncologic outcomes following, 3118–3119, 3118*t*
    - robotic, Robotic radical cystectomy
    - with transurethral resection of bladder tumor
        - female, 3141–3143, 3142*f*–3143*f*
        - male, 3138–3141, 3139*f*–3141*f*

Radical inguinal lymph node dissection, for penile cancer, 1796–1798, 1799*f*–1800*f*

Radical nephrectomy
    - laparoscopic, Laparoscopic radical nephrectomy
    - for malignancy, 2257–2261, 2257*f*
        - complications of, 2261
        - regional lymphadenectomy with, 2260, 2260*f*, 2260.e1*f*
        - surgical procedure for, 2257–2260, 2258*f*–2259*f*, 2258.e1*f*, 2259.e1*f*
        - wound closure for, 2261
    - for RCC, local recurrence after, 2164–2165, 2165–2166, 2165*b*, 2166*f*, 2167*t*, 2168*f*

Radical nephroureterectomy, for UTUC, 2199–2202
    - distal ureter and bladder cuff management, 2200

- indications of, 2199
- laparoscopic, 2202–2205
- open, 2199–2200, 2200*f*
- total laparoscopic technique in, 2202, 2203*f*
- traditional open distal ureterectomy in, 2200–2201, 2200*f*–2201*f*
- transurethral resection of ureteral orifice, 2201–2202, 2202*f*
- transvesical ligation and detachment technique in, 2201, 2201*f*

Radical orchiectomy, 1711
- technique for, 1711–1712
- for TGCTs, 1686

Radical pelvic irradiation, localized prostate cancer and, 3525

Radical prostatectomy
- biochemical recurrence after, 3659–3665, Biochemical recurrence, after radical prostatectomy
- for locally advanced prostate cancer, 3645–3652, 3648*b*
    - adjuvant androgen deprivation with, 3652
    - adjuvant radiation therapy, 3650–3652, 3651*t*, 3652*b*
    - for clinical stage T3, 3645–3652, 3646*t*
    - neoadjuvant androgen deprivation, 3648–3649, 3648*t*–3649*t*
    - neoadjuvant chemotherapy and chemotherapy-hormonal therapy, 3649–3650, 3650*t*
    - outcomes of, 3646–3647, 3647*f*
- pathologic findings with, 3643, 3643*t*
- and PD, 1602
- for prostate adenocarcinoma, 3510–3512
- for prostate cancer, hormonal therapy with, 3682
- retropubic, Retropubic radical prostatectomy
- salvage, Salvage radical prostatectomy
- urinary incontinence after
    - prevalence of, 2587
    - risk factors for, 2587
    - sphincteric function and, 2596

Radiofrequency ablation (RFA)
- for RCC, 2171
- for renal tumors, 2310–2312, 2312*b*
    - background and mode of action, 2310–2312
    - CA *versus*, 2317–2318
    - complications of, 2318–2319, 2320*f*–2321*f*, 2320*b*
    - equipment variations, 2311

    - follow-up for, 2312–2314, 2314*b*
    - intraoperative monitoring, 2311–2312
    - laparoscopic, 2304–2305
    - oncologic outcomes of, 2314–2318, 2315*t*–2316*t*, 2318*b*
    - percutaneous, 2312, 2313*f*, 2318
    - treatment temperature, 2311

Radiography
  - of bladder injuries, 3055–3056
  - of cloacal anomalies, 1024–1025
  - of defecation disorders, 669–670, 669*f*–670*f*
  - for genitourinary tuberculosis, 1311–1313, 1311*f*–1313*f*
  - intravenous urography, Intravenous urography
  - loopography, Loopography
  - of male pelvis, 2457–2458
  - of neuroblastoma, 1089
  - retrograde pyelography, Retrograde pyelography
  - retrograde urethrography, Retrograde urethrography
  - static cystography, Static cystography
  - for ureteropelvic junction obstruction, 1943, 1944*f*
  - of urethral diverticula, 2982–2983, 2983*f*–2984*f*
  - of urinary lithiasis, 2038
  - of urogenital sinus abnormalities, 1023–1024
  - voiding cystourethrogram, Voiding cystourethrogram

Radioisotopic penography, 1524

Radiologic imaging
  - of pediatric urology, 388
  - for UTUC, 2191–2192

Radionuclide cystography, 423, 424*f*–425*f*

Radionuclide renal scan, for posterior urethral valves, 608

Radionuclide studies, for UTIs, 1144.e1

Radionuclide testicular scanning, 423

Radiopharmaceuticals
  - for castration-resistant prostate cancer, 3704
  - for nuclear imaging of kidneys, 96*b*

Radiotherapy and Androgen Deprivation in Combination after Local Surgery (RADICALS), 3663–3664

Radiotracers, 91

Radium-223, for castration-resistant prostate cancer, 3704

RAE, Renal artery embolization

RaLPN, Robotic-assisted laparoscopic partial nephrectomy

RALRP, Robotic-assisted laparoscopic radical prostatectomy

Randall plaques, 2011, 2012*f*–2013*f*, 2018

Randolph technique, 595

Random flaps, for urethral and penile reconstruction, 1807, 1807*f*

Randomized Intervention for Management of Vesicoureteral Reflux (RIVUR) study, 515–516

RANK ligand inhibitors, for castration-resistant prostate cancer, 3704

Rapid eye movement (REM), 2665

RAS, Renal artery stenosis

RASSF1A gene, in bladder cancer, 1349

RAVES (Radiotherapy-Adjuvant Versus Early Salvage) trial, 3664–3665

RAZOR trial, of robotic cystectomy, 3144

RBF, Renal blood flow

RCC, Renal cell carcinoma

RCCT, Renal concentrating capacity test

Reactive arthritis

- as papulosquamous disorder, 1279–1280, 1280*f*
- urethral involvement in, reconstructive surgery for, 1808
    - for reactive arthritis, 1808
    - for urethral hemangioma process, 1808

Real-time CT fluoroscopy, 45

Real-time elastography (RTE), 74, 75*f*

- of scrotum, 84

Real-time or ultrasound dosimetry, 3598

Reanastomosis, for urethral stricture disease, 1819–1820, 1819*f*–1820*f*

Reboxetine, for delayed ejaculation, 1579

Reconstructive surgery

- after bladder RMS treatment, 1116
- for cloacal anomalies, 1037–1041, 1040*b*
  - definitive, 1039–1041, 1039*f*
  - gastrointestinal tract decompression for, 1038
  - genitourinary tract decompression for, 1038–1039, 1038*f*
  - initial management, timing, and principles for, 1037–1038
  - obstructive urinary repair, 1039
  - results of, 1040–1041, 1041*t*
- for detrusor underactivity, 2663
- for disorders of sex development and urogenital sinus
  - current operative techniques for, 1028–1034, 1029*f*
  - high vaginal confluence: with or without clitoral hypertrophy, 1030–1033, 1031*f*–1033*f*
  - initial management, timing, and principles, 1025–1028, 1026*f*
  - low vaginal confluence: clitoral hypertrophy, 1028–1030, 1030*f*, 1030*b*
  - results of, 1034–1037
  - total and partial urogenital mobilization, 1033–1034, 1034*f*–1036*f*
- microvascular, 3050
- penile and urethral, 1804–1842, 1805*b*, 1813*b*
  - for amyloidosis, 1810
  - anatomy of, 1807, 1807.e1*f*–1807.e7*f*
  - for balanitis xerotica obliterans, 939, 940*f*
  - for circumcision complications, 1811–1812
  - in classic bladder exstrophy, 551–552, 552*f*–553*f*
  - for curvatures of penis, 1836–1838, 1838*b*
  - for failed epispadias repair, 1813
  - for failed hypospadias repair, 1812–1813
  - female-to-male transgender, 1841–1842, 1842*b*
  - for fistulae of posterior urethra, 1835–1836, 1836*b*
  - for glans dehiscence, 937, 938*f*
  - for LS, 1808–1810, 1809*f*
  - in male epispadias, 569
  - for meatal stenosis, 937–938, 1811
  - for paraphimosis, balanitis, and phimosis, 1811
  - penile transplantation, 1838–1842, 1840*f*, 1842*b*
  - for PFUIs, 1828–1834, 1830*f*–1834*f*

    - principles of, 1804–1807, 1806*f*–1807*f*, 1808*b*
    - for reactive arthritis, 1808
    - for recurrent penile curvature, 939–941, 940*f*
    - for urethral diverticulum, 938–939, 939*f*, 1810–1811
    - for urethral hemangioma process, 1808
    - for urethral stricture, 938, 1814–1828, 1814*f*, 1828*b*
    - for urethrocutaneous fistula, 935–937, 936*f*–937*f*, 1810
    - for vesicourethral distraction defects, 1834*b*, 1835, 1836*b*

Rectal bladder urinary diversion, 3209–3211
  - augmented valved rectum, 3209
  - folded rectosigmoid bladder, 3209
  - hemi-Kock pouch procedures with valved rectum, 3209–3210
  - Mainz II pouch, 3210–3211
  - sigma-rectum pouch, 3210–3211
  - T pouch procedures with valved rectum, 3209–3210, 3210*f*

Rectal carcinoma, and delayed ejaculation, 1576

Rectal fascia, 2427, 2429*f*

Rectal injury
  - bowel injury and, 277–278
  - complications of seminal vesicle surgery, 1864

Rectal mucosal grafts, 1807

Rectal toxicity, prostate cancer and, 3603–3604

Rectocele, 2526, 2587
  - repair of, 2825

Rectourethral fistulae (RUF), 2955–2958, 2956*f*, 2958*b*

Rectouterine pouch, 2427–2428, 2429*f*

Rectovaginal space, 2427, 2429*f*

Rectovesical pouch, bladder, 3010

Rectum, anatomy of, 2449, 2450*f*, 2454, 2455*f*

Rectus abdominis, 136*f*, 2447, 2447*f*–2448*f*

Rectus muscle flap, in urethrovaginal fistulae, 2950

Rectus sheath, 2444, 2447*f*–2448*f*

Recurrent cryptorchidism, 949

Recurrent infection, in bladder tumor, 3077

Recurrent penile curvature, 913*f*–914*f*, 939–941, 940*f*

Recurrent stenosis, after urethral injury, 3060

Recurrent uric acid stone formation, ammonium acid urate stones from, 2032

Recurrent UTIs, 1159–1166, 1160*t*, 1160*b*

- ammonium acid urate stones from, 2032
- bacterial persistence and, 1160–1161
- cranberry, 1163–1164, 1164*f*
- D-mannose, 1166
- estrogen, 1164–1165, 1164*f*
- immunoactive prophylaxis, 1166
- low-dose continuous prophylaxis for, 1162–1163
- management, 1161–1166, 1161*f*
- methenamine, 1165*t*, 1166
- non-antibiotic management, 1163
- probiotics, 1165

REDUCE, Reduction by Dutasteride of Prostate Cancer Events

5α-Reductase

- in benign prostatic hyperplasia, 3307–3308, 3308*f*
- prostate metabolism, 3286–3287, 3286*f*, 3287*t*

5α-Reductase deficiency, 1014–1016, 1015*f*

5α-Reductase inhibitors
- α-adrenergic blockers and, 3385, 3386*f*
- for benign prostatic hyperplasia, 3378
- for chemoprevention of prostate cancer, 3473–3475
- for chronic scrotal pain syndrome, 1215
- to facilitate bladder filling and urine storage
  - with α-adrenoreceptor antagonists, 2707
  - with antimuscarinic agents, 2707
- for priapism, 1553
- prostate-specific antigen and, 3515

5α-Reductase-specific antibodies (5ARIs), in prostate cancer, 3544

Reduction by Dutasteride of Clinical Progression Events in Expectant Management of Prostate Cancer (REDEEM) study, 3544

Reduction by Dutasteride of Prostate Cancer Events (REDUCE), 3475

Re-entry catheter, 173, 174*f*

Reflection, of ultrasound waves, 71, 71*f*

Reflex circuitry
- controlling continence, 2489–2493, 2490*f*
  - somatic to visceral reflexes, 2492
  - sphincter to bladder reflexes, 2490*f*, 2491–2492, 2492*f*
  - storage phase, 2490–2491, 2490*f*–2491*f*, 2491*t*
- controlling micturition, 2489–2493, 2490*f*
  - emptying phase, 2490*f*, 2491*t*, 2492
  - urethra to bladder reflexes, 2492–2493, 2492*f*–2494*f*

Reflex contraction, promotion or initiation of, 2902

Reflex sympathetic dystrophy (RSD), lower urinary tract dysfunction and, 2626

Reflux nephropathy, 742

Reflux-associated renal dysplasia, 499, 499*f*, 499*t*, 499.e1*f*

Refluxing ureteral reimplantation, 3023–3026, 3023*f*

Refractory urinary storage symptoms, after urethrolysis, 2848

Regional anesthesia, in urologic surgery, 131–132

Regions of interest (ROI), 3587–3588

Regitine, Phentolamine

Reiter syndrome, Reactive arthritis

Relapse, tumors
- NSGCTs, 1700–1702
- seminomas, 1706

Relative jet frequency (RJF), 778

Relative saturation ratio (RSR), 2010

Reliability, definition of, 109

Religion, benign prostatic hyperplasia and, 3320–3321

REM, Rapid eye movement

Renal abscess, 1172–1174, 1172*f*–1173*f*

Renal agenesis, 741–742
- unilateral, Unilateral renal agenesis

Renal anomalies, 510

Renal arterial clamping, for laparoscopic partial nephrectomy, 2303

Renal arterial laceration, for pediatric genitourinary trauma, 1074

Renal arterial occlusion, for pediatric genitourinary trauma, 1074

Renal arteries, 1671–1672
- occlusion of, Ischemic nephropathy, Renovascular hypertension
- in radical nephrectomy, 2258, 2258*f*, 2258.e1*f*
- in simple nephrectomy, 2288, 2288*f*

Renal arteriovenous fistula, 737

Renal artery aneurysm (RAA), 736–737

Renal artery embolization (RAE), before kidney surgery, 2248, 2248.e1*f*

Renal artery stenosis (RAS)
- diagnosis of, 1916–1918, 1917*f*–1918*f*, 1918*b*
- incidence and etiology of, 1914*b*
- management of, 1918–1919

- medical therapy, 1918
- percutaneous intervention, 1918–1919, 1919*f*
- surgical, 1919, 1920*b*

pathophysiology of, 1915–1916, 1915*f*–1916*f*, 1915*t*, 1916*b*

- one-kidney, one-clip model of, 1917, 1918*f*
- two-kidney, one-clip model of, 1917, 1917*f*

in renovascular hypertension, 1915

screening tests for

- angiography, 1917–1918, 1918*b*
- CT, 1917–1918, 1918*b*
- duplex Doppler ultrasonography, 1917–1918, 1918*b*
- MRA, 1917–1918, 1918*b*

Renal artery thrombosis (RAT), 387

Renal bladder ultrasound, for pediatric urology, 388–389

Renal bleeding

nephrectomy and, 1988–1989

with renal injury, 1991

Renal blood flow (RBF), 1905, 1906*b*

aging and, 2905

urinary tract obstruction and

- in bilateral ureteral obstruction, 791–792
- GFR and, 791
- renal vascular resistance and, 791
- in unilateral ureteral obstruction, 791

Renal calculi, 2069.e1, 2084*b*

ammonium acid urate stones in, 2032

anatomic predisposition to, 2033–2035

- caliceal diverticula, 2034
- horseshoe kidneys, 2034
- medullary sponge kidney, 2034–2035
- ureteropelvic junction obstruction, 2034

calcium stones in, 2018–2026

- hypercalciuria, 2018–2020
- hyperoxaluria, 2020–2023, 2021*f*–2022*f*
- hyperuricosuria, 2023–2024, 2024*f*
- hypocitraturia, 2024
- hypomagnesiuria, 2026

classification of, 2017–2018, 2017*t*–2018*t*

clinical factors of, 2088–2091, 2091*b*
  duration, 2091
  morbid obesity and, 2089
  old age and frailty, 2089–2090
  prior renal surgery, 2090
  renal function, 2088–2089
  renal transplants, 2091
  solitary kidney, 2089
  spinal deformity or limb contractures, 2090
  uncorrected coagulopathy, 2090
  urinary diversion, 2091
  urinary tract infection and, 2088
composition of, treatment decision based on, 2076
cystine stones in, 2029–2030, 2029*f*
dihydroxyadenine stones in, 2031–2032
epidemiology of, 2005–2009, 2009*b*
  age, 2006
  cardiovascular disease, 2008–2009
  chronic kidney disease, 2009
  climate, 2007
  gender, 2005–2006
  geography, 2006–2007, 2007*f*
  obesity, diabetes, and metabolic syndrome, 2008
  occupation, 2007–2008
  race and ethnicity, 2006
  water intake, 2009
infection stones in, 2030–2031
  bacteriology of, 2030–2031, 2031*t*
  epidemiology of, 2031
  pathogenesis of, 2030, 2030*f*
matrix stones in, 2032
medication-related stones in, 2032–2033
mineral metabolism and, 2015–2017, 2017*b*
  calcium, 2015–2016
  magnesium, 2016
  oxalate, 2016–2017
  phosphorus, 2016
natural history of, 2069–2070
nonmedical management of, 2069–2093
  anatomic factors in, 2077–2084
  in calyceal diverticula, 2077–2078, 2077.e1*f*
  factors affecting, 2070*b*

    - imaging for, 2071
    - laboratory tests for, 2071
    - lower pole calculi, 2081–2084, 2081*f*, 2082*t*, 2083*f*
    - medical history for, 2071
    - pretreatment assessment for, 2070–2071
    - in renal ectopia, 2080–2081, 2081*f*
    - stone burden and treatment decision, 2072–2074, 2072*b*, 2073*f*
    - stone composition and, 2076
    - stone localization and, 2075–2076
    - treatment algorithm for, 2069, 2070*f*
    - in ureteropelvic junction obstruction, 2077
  - nonstaghorn, Nonstaghorn renal calculi
  - pathophysiology of, 2017–2035, 2035*b*
  - physicochemistry of, 2009–2015, 2015*b*
    - inhibitors and promoters, 2014–2015
    - matrix of, 2015
    - nucleation and crystal growth, 2010–2014, 2012*f*–2013*f*
    - saturation state in, 2009–2010, 2010*f*–2011*f*
  - in pregnancy, 2035
  - staghorn, Staghorn calculi
  - technical factors of, 2088
  - uric acid stones in, 2026–2029, 2027*f*–2028*f*
    - hyperuricosuria, 2029
    - low urinary volume, 2029
    - low urine pH, 2027–2029, 2028*f*
  - with urinary intestinal diversion, 3180*t*, 3195–3196
  - in urinary tract obstruction, 778
  - xanthine stones in, 2031–2032
- Renal calyces, 1869, 1869.e1*f*
- Renal cell carcinoma (RCC)
  - autosomal dominant polycystic kidney disease association with, 753, 2158
  - clear cell type, 55
  - clinical associations of, 2156–2158
  - clinical presentation of, 2155–2156, 2156*t*, 2156*b*
  - etiology of, 2140–2141, 2141*b*
  - familial, 2141–2145, 2142*t*–2143*t*, 2144*f*
    - treatment of, 2173–2174, 2174*f*
  - historical considerations for, 2133
  - incidence of, 2138–2140

metastatic, Metastatic RCC

as non-AIDS-defining urologic malignancy, 1268

pathology of, 2148–2155, 2148*t*–2151*t*, 2153*b*

- chromophobe RCC, 2149*t*–2151*t*, 2152–2153, 2154*f*
- classification systems, 2149–2151, 2149*t*–2151*t*
- clear cell RCC, 2149*t*–2151*t*, 2151–2152, 2152*f*
- collecting duct RCC, 2149*t*–2151*t*, 2154
- papillary RCC, 2149*t*–2151*t*, 2152, 2153*f*
- renal medullary RCC, 2149*t*–2151*t*, 2154–2155
- sarcomatoid and rhabdoid differentiation, 2149*t*–2151*t*, 2155, 2155*f*
- unclassified, 2149*t*–2151*t*, 2155

in pediatric patients, 1109–1110

prognosis of, 2160–2162, 2161*t*

screening for, 2156–2158, 2157*t*

staging of, 2158–2160, 2158*t*–2159*t*, 2160*f*, 2160*b*

treatment of advanced, 2325–2328

- chemotherapy, 2341–2342
- debulking or cytoreductive nephrectomy, 2325–2328, 2326*f*–2327*f*, 2327*t*, 2328*b*
- hormonal therapy, 2342–2343
- palliative surgery, 2328, 2328*b*
- prognostic factors and, 2324–2325, 2325*f*, 2325*t*
- resection of metastases, 2328, 2328*b*
- systemic therapy for non-clear cell variants, 2343–2344, 2344*f*
- targeted molecular agents in, 2324, 2333–2341, 2333*t*–2335*t*, 2336*f*, 2337*t*

treatment of localized, 2162–2174

- active surveillance, 2173, 2173*t*
- AUA guidelines for, 2162–2163, 2163*f*
- nephron-sparing surgery in, 2173–2174, 2174*f*
- partial nephrectomy, 2164–2169, 2165*b*, 2167*t*, 2169*f*
- radical nephrectomy, 2164–2165, 2165–2166, 2165*b*, 2166*f*, 2167*t*, 2168*f*
- risk stratification and renal mass biopsy, 2163–2164, 2164*f*, 2164*b*
- thermal ablative therapies, 2171–2173, 2171*f*, 2172*t*
- tumor enucleation, 2170–2171, 2170*f*

treatment of locally advanced, 2174–2180, 2174*b*

- adjuvant therapy, 2178–2180, 2178*b*
- IVC involvement, 2174–2176, 2175*f*–2176*f*, 2298, Vena caval thrombectomy
- local recurrence, 2178, 2178*b*
- locally invasive, 2176–2177
- lymph node dissection, 2177–2178, 2177*f*, 2177*t*, 2260, 2260*f*, 2260.e1*f*

with tuberous sclerosis complex, 758

tumor biology clinical implications in, 2145–2148

- angiogenesis and targeted pathways, 2146, 2148

    - cancer genome research, 2146–2148
    - immunobiology and immune tolerance, 2145–2146, 2147*f*
    - resistance to cytotoxic therapy, 2145, 2145*t*

Renal clearance, 1905

Renal concentrating capacity test (RCCT), 2678

Renal cortex, 1866, 1866.e1*f*

Renal cortical scintigraphy, 390

Renal cystic diseases, 745–746, 746*f*
- acquired, Acquired renal cystic diseases
- benign multilocular cyst, 765–766, 765*f*, 766*b*, 767*f*
- classification of, 745–746, 745*b*
- congenital nephrosis, 756
- familial hypoplastic glomerulocystic kidney disease, 756–757
- inheritable, 745*b*, 746
- medullary, 747*t*, 755–756, 756*f*, 756*b*
- medullary sponge kidney, 771–772, 771*f*, 772*b*
- multicystic dysplastic kidney, 762–765, 762*f*, 765*b*
- multiple malformation syndromes, 747*t*, 762*b*
- polycystic, 751*t*
    - autosomal dominant, 750–755, 755*b*
    - autosomal recessive, 746–749, 751*b*

Renal cysts, 401–402, 405, 2121–2123, 2123*b*
- epidemiology, etiology, and pathophysiology of, 2121
- evaluation of, 2122, 2122*f*, 2122*t*
- laparoscopic surgery for, 2291–2292, 2291*f*
    - procedure for, 2291, 2291*f*
    - results of, 2291–2292
- management options of, 2123, 2123*f*
- multiple malformation syndromes with, Multiple malformation syndromes with renal cysts
- natural history of, 2121–2122
- papillary adenoma, of kidney, 2128, 2128*b*

Renal descensus, for ureteral stricture disease, 1973

Renal drainage, for urinary tract obstruction, 795

Renal dysfunction, HIV and, 1266–1267

Renal dysplasia, 741–742, 741*b*
  definition of, 741, 742*f*
  etiology of, 741–742, 742*f*–743*f*
Renal echinococcosis, 1181.e1, 1181.e2*f*
Renal ectopia, 1869, 1869.e1*f*
  cephalad, 724–725, 726*f*
  crossed, 727–728, 728*f*, 731*b*
  simple, 724*f*–725*f*
Renal exploration
  for pediatric genitourinary trauma, 1073
  for renal injuries, 1988–1989, 1988*f*
Renal (Gerota) fascia, 1865
Renal function
  after RCC surgery, 2164–2169, 2165*b*, 2167*t*, 2169*f*
  aging and, 2905
  orthotopic urinary diversion and, 3237–3238
  in posterior urethral valves, 619, 620*b*
  in prune-belly syndrome, 595–596
  upper urinary tract calculi and, 2088–2089
Renal functional assessment
  for benign prostatic hyperplasia, 3345–3346
  for ureteral anomalies, 806, 806*f*
Renal hilum, 1865, 1869
  identification of, for simple nephrectomy, 2287–2288, 2288*f*
Renal hypercalciuria, 2019–2020
Renal hypodysplasia, 742–745, 745*b*
Renal hypoplasia, 742–745, 745*b*
Renal infection (bacterial nephritis), 1166–1177
  acute focal or multifocal bacterial nephritis, 1171.e1, 1171.e1*f*
  for acute pyelonephritis, 1168–1171, 1168*f*–1169*f*, 1170*t*
  bacterial “relapse,”, 1177.e1

- chronic pyelonephritis, 1176–1177, 1177*f*
- emphysematous pyelonephritis, 1171–1172, 1171*f*
- HIV and, 1266
- infected hydronephrosis and pyonephrosis, 1174, 1174*f*
- pathology, 1166–1168, 1167*f*–1168*f*
- perinephric abscess, 1174–1176, 1175*f*
- renal abscess, 1172–1174, 1172*f*–1173*f*

Renal injuries, 1982–1992, 1992*b*

- angioembolization for, 1986, 1986*f*
- classification of, 1983–1986, 1983*f*, 1983*t*
- damage control for, 1991
- genitourinary trauma and, 1075–1076
- hematuria in, 1982–1983
- history for, 1982–1983
- imaging of
  - CT, 1984–1985, 1984*f*–1985*f*
  - indications for, 1984, 1984*f*
  - IVP, 1985
- in intraoperative consultation, 302–303
  - diagnosis/recognition, 302–303
  - incidence, 302
  - management, 303
  - mechanisms, 302
- nonoperative management of, 1986–1988, 1987*f*
- operative management of, 1988–1991
  - complications with, 1991–1992
  - indications for, 1991
  - partial nephrectomy, 1989–1990, 1989*f*
  - renal exploration for, 1988–1989, 1988*f*
  - renal reconstruction, 1989–1991, 1989*f*–1990*f*
  - renorrhaphy, 1989, 1989*f*
  - for renovascular injuries, 1990–1991, 1990*f*–1991*f*
  - total nephrectomy, 1991
- pediatric, 1065
- presentation of, 1982–1983
- renal trauma grading system for, 1066–1072, 1067*f*–1069*f*, 1067*t*, 1069*t*

Renal insufficiency, 1921–1935

- bacteriuria in pregnancy and, 1187.e1

- metabolic syndrome and, 1420
- partial nephrectomy causing, 2266

Renal ischemia, Ischemic nephropathy, Renovascular hypertension
- for laparoscopic partial nephrectomy, 2303–2304
- for partial nephrectomy, 2262, 2262*f*

Renal magnetic resonance imaging, 55–67, 59*f*–60*f*

Renal malignancies, 2133–2184, 2134*t*
- chronic inflammation role in, 1336
- classification of, 2133–2134, 2137*t*
- genomic alterations in, 1353, 1354*t*, 1358
- hereditary, Hereditary leiomyomatosis and RCC syndrome, Hereditary papillary RCC syndrome
- historical considerations for, 2133
- immune checkpoint blockade in, 1343
- lymphoma and leukemia, 2181–2183, 2182*t*
- metastases, 2181*t*, 2183
- other, 2181*t*, 2183–2184
- port-site recurrence of, 2297
- radiographic evaluation of, 2134–2138, 2135*t*, 2136*f*
  - CT, 2134–2135, 2136*f*, 2174*f*
  - for cystic lesions, 2137–2138, 2139*f*–2140*f*
  - MRI, 2135, 2138*f*
  - ultrasonography, 2135
- RCC, 2138–2162, Renal cell carcinoma
- sarcomas, 2180–2181, 2181*t*, 2182*f*
- surgical techniques for, Kidney surgery
- vaccines for, 1339–1340

Renal medulla, 1866, 1866.e1*f*–1866.e2*f*, 1867*f*

Renal medullary RCC, pathology of, 2149*t*–2151*t*, 2154–2155

Renal morphogenesis, 341

Renal osteodystrophy, 355

Renal pain, patient history of, 2

Renal papilla, 1866, 1866.e1*f*–1866.e2*f*

Renal papillary necrosis (RPN), host defense mechanisms in UTIs and, 1139–

1140, 1139*b*

Renal parenchyma, 161–162

radiologic anatomy of, 1868–1869, 1868*f*, 1868.e1*f*, 1869*b*, 1869.e1*f*–1869.e2*f*

Renal pelvic perforation, 179, 180*f*

Renal pelvis

normal upper tract urothelium, 2188

physiology of, 1877–1904

rupture of, for pediatric genitourinary trauma, 1075

urothelial neoplasms, 2188–2189

Renal physiology, 1905–1920

hormonal, renal hormone effects, 1913–1914, 1913*f*–1914*f*, 1914*b*

vascular

blood flow, Renal blood flow

glomerular filtration, Glomerular filtration rate

Renal preservation surgery, urinary leak after, 2962

Renal rotation, anomalies of, 733–735, 735*b*

description for, 733

diagnosis of, 734, 735*f*

dorsal position in, 733

incidence of, 733

lateral position in, 733–735

prognosis of, 735

symptoms of, 734

ventral position in, 733

ventromedial position in, 733

Renal scintigraphy, 367–369, 369*f*–370*f*, 390

diuretic renography, 390

renal cortical scintigraphy, 390

Renal sinus, 1865

cyst of, 775, 775*f*

Renal stones, 406

metabolic syndrome and, 1420–1421

- Renal threshold, 19–20
- Renal transplantation
  - evaluation, 94–95
  - genitourinary tuberculosis management and, 1318–1319
  - pediatric, Pediatric renal transplantation
  - in posterior urethral valves, 619–620
  - urinary leak after, 2962
  - urologic complications of, 1936–1941
    - genitourinary malignancies, 1940–1941, 1941*b*
      - bladder cancer, 1941
      - prostate cancer, 1941
      - renal cell carcinoma, 1940–1941, 1940*f*
    - hematuria, 1936
    - lower urinary tract complications, 1939–1940
      - benign prostatic hyperplasia, 1939
      - transplant, small bladder after, 1939
      - urine incontinence, 1939–1940
      - voiding dysfunction, 1939
    - lymphocele, 1938–1939
    - nephrolithiasis, 1939
    - ureteral leak, 1937, 1937*b*
    - ureteral stent management, 1936, 1936*b*
    - ureteral structure, 1937–1938, 1937*t*, 1938*b*
    - vesicoureteral reflux, 1938
- Renal trauma, Renal injuries
- Renal tubular acidosis (RTA)
  - in calcium stone formation, 2025–2026, 2025*f*
  - type 1 (distal), 2025–2026, 2025*f*
  - type 2 (proximal), 2026
  - type 4 (distal), 2026
- Renal tubular disorders, 348, 349*b*
- Renal tubules
  - apoptosis in, 790
  - urinary tract obstruction and, 791
- Renal tumors, 402
  - benign, 2121–2132, Renal cysts
    - angiomyolipoma, 2125–2128, 2126*f*–2127*f*, 2128*b*
    - cystic nephroma, 2129–2130, 2129*f*
    - diagnosis of, 2121

- leiomyoma, 2131, 2131*f*, 2131*b*
- metanephric adenoma, 2128–2129, 2129*f*, 2129*b*
- mixed epithelial and stromal, 2130, 2130*f*, 2130*b*
- mixed mesenchymal and epithelial, 2129–2130, 2129*f*
- oncocytoma, 2123–2125, 2124*f*, 2125*b*
- other, 2131–2132, 2132*b*
- papillary adenoma, of kidney, 2128, 2128*b*

imaging and clinical risk stratification of, 2133–2134, 2135*t*

malignant, Renal malignancies

nonsurgical focal therapy of, 2309–2323

- complications, 2318–2319, 2320*f*–2321*f*, 2320*b*
- cryoablation, 2309–2310, 2310*b*, Cryoablation (CA), for renal tumors
- new ablation modalities, 2319–2323, 2323*b*
- oncologic outcomes, 2314–2318, 2315*t*–2316*t*, 2318*b*
- radiofrequency ablation, 2310–2312, 2312*b*
- surgical technique, 2312
- treatment success and follow-up protocol after tumor ablation, 2312–2314, 2314*b*

pediatric

- angiomyolipoma, 1110, 1110*f*
- CCSK, 1108–1109
- CMN, 1109
- CPDN, 1109
- metanephric adenofibroma, 1109
- neuroblastoma, Neuroblastoma
- RCC, 1109–1110
- RTK, 1109
- solitary multilocular cyst nephroma, 1109
- Wilms tumor, Wilms tumor

radiologic evaluation of, 2134–2138, 2135*t*, 2136*f*

- CT, 2134–2135, 2136*f*, 2174*f*
- for cystic lesions, 2137–2138, 2139*f*–2140*f*
- MRI, 2135, 2138*f*
- ultrasonography, 2135

surgical techniques for, Kidney surgery

Renal ultrasonography

for acute pyelonephritis, 1168

indications for, 78

limitations of, 80

normal findings in, 78–79, 79*f*

procedural applications of, 79–80

technique of, 78

Renal vascular development, 338–340

Renal vascular hypertension, evaluation of, 94

Renal vasculature

- anomalies of, 735–736, 737*b*
  - aberrant, accessory, or multiple vessels, 735–736, 736*f*
  - renal arteriovenous fistula, 737
  - renal artery aneurysm, 736–737
- hormonal, renal hormone effects, 1913–1914, 1913*f*–1914*f*, 1914*b*

Renal vein thrombosis, AKI caused by, 1925

Renal vein tumor thrombus, laparoscopic radical nephrectomy for, 2298

Renal veins, 1673, 1869–1870

- in radical nephrectomy, 2258, 2258*f*, 2258.e1*f*
- in simple nephrectomy, 2288, 2288*f*

Renal/abdominal solid masses, 405–406

Renin-angiotensin system (RAS), erectile dysfunction and, 1493

Reninoma, 2132

Renography

- diuretic, Diuretic renography
- normal curve of, 779
- nuclear, for urinary tract obstruction, 779
- in transitional urology, 1048

Renomedullary interstitial cell tumors, 2132

Renorrhaphy, for renal injuries, 1989, 1989*f*

Renovascular fistulae, 2958

Renovascular hypertension, 1915–1919

- diagnosis of, 1916–1918, 1917*f*–1918*f*, 1918*b*
- incidence and etiology of, 1914*b*
- management of, 1918–1919
  - medical therapy, 1918
  - percutaneous intervention, 1918–1919, 1919*f*
  - surgical, 1919, 1920*b*
- pathophysiology of, 1915–1916, 1915*f*–1916*f*, 1915*t*, 1916*b*

    - one-kidney, one-clip model of, 1917, 1918*f*
    - two-kidney, one-clip model of, 1917, 1917*f*
  - screening tests for
    - angiography, 1917–1918, 1918*b*
    - CT, 1917–1918, 1918*b*
    - duplex Doppler ultrasonography, 1917–1918, 1918*b*
    - MRA, 1917–1918, 1918*b*

Renovascular injuries, operative management of, 1990–1991, 1990*f*–1991*f*

Reoperative RPLND, 1728*t*, 1729

Replantation, of penis, 3050–3051

Reports, ultrasonography, 76–77

Reproductive system
  - female, Female reproductive system
  - male, Male reproductive system

Residual tumor, after treatment
  - NSGCTs with, 1698–1700, 1698*t*–1699*t*
  - seminomas with, 1705–1706

Resiniferatoxin, 2485
  - to facilitate bladder filling and urine storage, 2682*t*, 2709
  - in idiopathic detrusor overactivity, 2709.e1
  - in neurogenic detrusor overactivity, 2709.e1
  - urgency and, 2709.e1

Resistance, to chemotherapy, RCC with, 2145, 2145*t*

Resolution, of ultrasonography images, 70–71, 70*f*

Resorptive hypercalciuria, 2020

Respiratory system
  - aging and, 2906
  - pneumoperitoneum effects on, 221

Response Evaluation Criteria In Solid Tumors (RECIST), 104, 105*t*

Resting membrane potential (RMP), of ureteral muscle cells, 1878–1879, 1879*f*, 1881, 1881*b*

Restriction point, RB1 and, 1347.e1, 1347.e1*f*

Rete testis, 1393
  adenocarcinoma of, 1708
  cystic dysplasia of, 899
Retention sutures, 151
Retinoblastoma susceptibility protein (RB1), in GU cancers, 1347.e1, 1347.e1*f*
13-*cis*-Retinoic acid, for neuroblastoma, 1095–1096
Retractile testis, 949, 1855
Retraction instrumentation, for laparoscopic and robotic surgery, 218
Retrocaval ureter
  etiology and diagnosis of, 1963, 1965*f*, 1966*b*
  operative intervention for, 1963–1965, 1965*f*
    laparoscopic surgical intervention, 1963–1965
Retrocrural disease, resection of, 1720, 1721*f*
Retrograde ejaculation, 1451
  after transurethral needle ablation of prostate, 3433
  with holmium laser enucleation of prostate, 3438
  with transurethral incision of prostate, 3435
  treatment of, 1579, 1580*b*
Retrograde injection, of male stress urinary incontinence, 2896, 2897*f*
Retrograde intrarenal surgery, Ureterorenoscopy
Retrograde pyelography, 36–38, 415
  complications, 38, 38*f*
  for genitourinary tuberculosis diagnosis, 1312–1313
  indications, 37
  limitations, 37
  technique, 36–37, 37*f*
  of urinary tract obstruction, 780–781
Retrograde renal access drainage, 182–184, 184*b*
  guide wire placement of, 183, 183*f*
  history, 182
  indications, 182

    - stent placement of, 183, 183*f*
    - stent tolerance, 184
    - stent varieties of, 183–184
        - design, 183–184, 184*f*
        - materials, 183
    - surgical technique of, 182–183
- Retrograde ureterography, of ureteral injuries, 1995
- Retrograde ureteroscopic endopyelotomy, for ureteropelvic junction obstruction, 1949–1950
    - complications of, 1950
    - indications and contraindications for, 1950
    - other, 1950
    - results with, 1950
    - technique for, 1950, 1951*f*–1952*f*
- Retrograde ureteroscopic endoureterotomy, for ureteral stricture disease, 1968–1969, 1969*f*
    - antegrade approach combined with, 1969
- Retrograde urethrography, 38, 39*f*
- Retroiliac ureter, 824
- Retroperitoneal approach, 832
    - to laparoscopic adrenalectomy, 2417–2418, 2418*f*, 2422
    - for laparoscopic and robotic surgery, 1956
        - operative team placement for, 207, 207*f*
    - to laparoscopic kidney surgery, 2279–2281, 2282*f*
    - to laparoscopic partial nephrectomy, 2300
- Retroperitoneal cancer of unknown primary origin, retroperitoneal tumors and, 2238
- Retroperitoneal fibrosis (RPF), 1981*b*
    - evaluation of, 1978–1979
    - management of
        - initial, 1979
        - medical, 1979–1980
        - surgical, 1980, 1981*f*
    - presentation and etiology of, 1977–1978

Retroperitoneal incision, for renal exploration, 1988, 1988*f*

Retroperitoneal lymph node dissection (RPLND), 1713–1717, 1713*f*, 2240–2241, 2241*f*, 2241*t*

- auxiliary procedures for, 1717–1720, 1721*b*
  - hepatic resection, 1719–1720
  - major vascular reconstruction, 1718–1719, 1719*f*
  - nephrectomy, 1718, 1718*t*
  - pelvic resection, 1720
  - supradiaphragmatic disease, management of, 1720
- complications of, 1730–1731, 1730*t*
  - chylous ascites, 1731
  - ileus, 1731
  - lymphocele, 1731
  - mortality, 1731
  - neurologic, 1731
  - pulmonary, 1730
  - VTE, 1731
- high-risk
  - desperation, 1728, 1728*t*
  - late relapse, 1728*t*, 1729
  - reoperative, 1728*t*, 1729
  - salvage, 1727–1728, 1728*t*
- laparoscopic, Laparoscopic retroperitoneal lymph node dissection
- management of clinical complete remission to induction chemotherapy, 1721–1722, 1722*t*
- for NSGCTs, 1694–1695, 1695*t*
- outcomes and functional considerations of
  - fertility, 1729–1730
  - lymph node counts, 1729
- in paratesticular RMS, 1126
- preoperative planning for, 1713–1714
- robotic, Robotic-assisted retroperitoneal lymph node dissection
- surgical technique for, 1714–1717
  - closure and postoperative care, 1717
  - gonadal vein dissection, 1716
  - interaortocaval packet, 1715–1716, 1716*f*
  - left para-aortic packet, 1714–1715
  - nerve sparing, 1716–1717, 1717*f*
  - retroperitoneum exposure, 1714, 1714*f*
  - right paracaval packet, 1716
  - split and roll technique, 1714, 1715*f*

  - template use in, 1722–1723, 1723*f*, 1723*t*
  - TGCT staging with, 1689–1690
  - in unique situations, 1731–1733, 1733*b*
    - for seminoma, 1731–1732
    - for sex cord stromal tumors, 1732–1733

Retroperitoneal tumors (RPTs), 2226–2247
  - anatomic considerations of retroperitoneum, 2226, 2226*b*
  - differential diagnosis of, 2227–2238, 2228*t*, 2238*b*
    - cystic change of solid retroperitoneal tumors, 2238
    - cystic lymphangioma, 2237, 2237*f*
    - cystic masses, 2236–2237
    - cystic mesothelioma, 2238
    - desmoid tumor, 2234, 2234*f*
    - Ewing and Ewing-like sarcoma, 2232–2233, 2233*f*
    - germ cell tumor, 2227–2229
    - germ cell/gonadal origins, 2227
    - hematologic conditions/lymphomas of retroperitoneum, 2236
    - leiomyosarcoma, 2231, 2231*f*
    - liposarcoma, 2229–2230, 2230*f*
    - lymphomas, 2236, 2237*f*
    - malignant fibrous histiocytoma/undifferentiated pleomorphic sarcoma, 2231, 2232*f*
    - mesodermal origins, 2229
    - mucinous cystadenoma, 2237
    - nerve sheath tumors, 2235–2236, 2236*f*
    - neurogenic origins, 2234
    - paraganglionic system tumors, 2235, 2235*f*
    - perivascular epithelioid cell tumor, 2234
    - plasmacytoma, 2236
    - pleomorphic liposarcoma, 2230–2231
    - retroperitoneal cancer of unknown primary origin, 2238
    - sex cord stromal tumor, 2229
    - solitary fibrous tumor, 2232, 2233*f*
    - sympathetic ganglia tumors, 2234–2235, 2235*f*
    - synovial sarcoma, 2231–2232, 2232*f*
    - unclassified sarcomas, 2233
  - disease-specific neoadjuvant and adjuvant therapies for, 2245–2247, 2246*t*, 2247*b*
  - initial evaluation of, 2226–2227, 2227*b*
  - surgical management of, 2238–2245, 2245*b*
    - auxiliary procedures for, 2242–2243
    - complications of, 2243–2244
    - modifications for, 2240–2243
    - postoperative care in, 2244–2245

    preoperative considerations, 2238
    technique for, 2238–2240
    template considerations for management of metastatic germ cell tumors, 2240–2242, 2241*f*, 2241*t*
    vascular reconstruction in, 2243

Retroperitoneum
  anatomic considerations of, 2226, 2226*b*
  anatomy of, 1658–1679, 1659*f*–1661*f*, 1659*t*, 1661*b*, 1666*b*
    10th, 11th, and 12th ribs, 1658–1665, 1658.e1*f*, 1665*f*
    arterial system, 1669–1672, 1669.e1*f*–1669.e2*f*, 1671*f*, 1671.e1*f*, 1672*t*
    body surface landmarks, 1658, 1662*f*
    fasciae and spaces, 1666–1668, 1666.e1*f*, 1667*f*–1668*f*, 1668*b*, 1674*b*
    gastrointestinal viscera, 1668–1669, 1668.e2*f*, 1669*f*–1670*f*, 1674*b*
    lumbodorsal fascia, 1665–1666, 1666*f*, 1666.e1*f*
    lymphatic system, 1674, 1675*f*
    nervous structures, 1674–1679, 1679*b*
    posterior abdominal wall, 1658, 1662*f*–1664*f*, 1664*t*
    psoas, iliacus, quadratus lumborum, and erector spinae, 1658, 1662*f*–1665*f*, 1664*t*
    spine, 1658, 1658.e1*f*
    vasculature, 1669–1674
    venous system, 1672–1674, 1672.e1*f*
  approach to, 2239–2240
  exposure of, 2239, 2239*f*
  exposure of, for RPLND, 1714, 1714*f*
  interaortocaval region in, 2240
  left para-aortic region in, 2239–2240
  right paracaval region in, 2240
  split-and-roll technique for, 2239, 2239*f*

Retropubic mid-urethral slings
  anatomy of, 2850
  complications of, 2863–2866
  outcomes for, 2854–2856, 2855*t*
  surgical approach to, 2851–2853, 2852*f*–2853*f*

Retropubic radical prostatectomy (RRP)
  accessory pudendal artery preservation in, 3552, 3552*f*
  anesthesia for, 3551–3552, 3551*f*
  bladder neck division, 3559–3560, 3560*f*–3561*f*
  bladder neck reconstruction and anastomosis, 3560–3562, 3561*f*–3562*f*
  complications with, 3563–3564

        - bladder neck contracture, 3564
        - erectile dysfunction, 3564
        - intraoperative, 3563
        - postoperative, 3563–3564
        - thromboembolic events, 3563
        - urinary incontinence, 3564
    - dorsal vein complex division, 3553–3554, 3554*f*
    - dorsal vein complex ligation, 3553–3556, 3553*f*
    - endopelvic fascia incision for, 3552, 3552*f*
    - exposure for, 3552
    - incision for, 3551–3552, 3551*f*
    - instruments for, 3551
    - lateral pedicles division in, 3558–3559, 3560*f*
    - lymphadenectomy in, 3551–3552, 3551*f*
    - neurovascular bundle in, 3555–3556
        - high anterior release of, at apex, 3557–3558, 3558*f*–3559*f*
        - identification of, 3556–3558
        - preservation of, 3556–3557, 3556*f*–3557*f*
        - wide excision of, 3558, 3559*f*
    - posterior dissection in, 3558–3559, 3560*f*
    - postoperative management for, 3562–3563
    - preoperative preparation for, 3550–3551
    - puboprostatic ligament division for, 3552, 3552*f*
    - seminal vesicle excision in, 3559–3560, 3560*f*–3561*f*
    - surgical anatomy of, 3548–3550, 3564*b*–3565*b*
        - pelvic fascia, 3549–3550, 3550*f*
        - pelvic plexus, 3548, 3549*f*
        - striated urethral sphincter, 3549, 3549*f*–3550*f*
        - venous and arterial, 3548, 3549*f*
    - surgical technique for, 3550–3563
    - urethra division and suture placement, 3554–3555, 3555*f*
- Retropubic simple prostatectomy, 3450–3452
    - adenoma enucleation for, 3451–3452, 3451*f*–3452*f*
    - hemostatic maneuvers in, 3451, 3451*f*
    - prostate exposure for, 3450, 3451*f*
- Retropubic space, bladder, 3010
- Retropubic suspension surgery, for incontinence in women, 2756–2775

- comparisons with, 2771–2774
    - anterior repair, 2771, 2771*b*
    - needle suspension, 2771, 2771*b*
    - pubovaginal sling, 2771–2773, 2772*f*, 2773*b*
    - between techniques, 2773
    - tension-free vaginal tape procedure, 2773–2774, 2774*b*
- complications of, 2769–2771, 2771*b*
    - bladder overactivity, 2770
    - postoperative voiding difficulty, 2770
    - vaginal prolapse, 2770–2771
- hypermobility in, 2757
- indications for, 2759–2761, 2760*f*
- intrinsic sphincter deficiency
    - contribution, 2757
    - issues of, 2759
- key points for, 2775*b*
- laparoscopic, 2768–2769, 2769*b*
- outcomes, assessment for
    - cure, definition of, 2759
    - follow-up, duration of, 2759
    - patient's *versus* physician's perspective, 2759
- potential contraindications for, 2760
- surgical procedures for, 2756–2757, 2757–2759, 2757*b*
    - Burch colposuspension, 2757–2758, 2758*f*, Burch colposuspension
    - Marshall-Marchetti-Krantz procedure, 2757–2758, 2758*f*, Marshall-Marchetti-Krantz procedure
    - paravaginal defect repair, 2757–2758, 2758*f*, Paravaginal repair
    - vagino-obturator shelf repair, 2757–2758, 2758*f*, Vagino-obturator shelf repair
- technical issues for, 2761–2762
    - bladder drainage for, 2761
    - dissection for, 2761
    - drains for, 2762
    - suture material for, 2761
- technique, choice of, 2757–2759
- therapeutic options for, 2756–2757, 2757*b*
- use of synthetic mesh in, 2774
- vaginal surgery *versus*, 2760–2761, 2761*b*

Retropulsion prevention devices, for ureteroscopic intraluminal lithotripsy, 198, 198*f*

Retrorectal space, 2427, 2429*f*

Reverberation artifact, in ultrasonography, 73, 73*f*–74*f*

Review of systems, patient history of, 9

RFA, Radiofrequency ablation

Rhabdoid differentiation, 2149*t*–2151*t*, 2155, 2155*f*

Rhabdoid tumor of kidney (RTK), in pediatric patients, 1109

Rhabdomyolysis, after laparoscopic and robotic surgery, 231

Rhabdomyosarcoma (RMS), 986, 986*f*

- bladder, Bladder RMS
- cervical or uterine, in pediatric patients, 1120
- paratesticular, in pediatric patients, 1126–1127, 1127*b*
- perineal, 1127, 1127*f*
- of prostate, 3512
- of testicular adnexa, 1709
- vaginal, in pediatric patients, 1119–1120, 1119*f*
- vulvar, in pediatric patients, 1119

Rhabdosphincter, 2467

- male sphincteric mechanisms and, 2594

Rho kinase signaling pathway, 1495, 1497*f*

RhoA, 2473, 2473*f*

Rhythmic suprapubic manual pressure, 2902

Ribs, in retroperitoneum, 1658–1665, 1658.e1*f*, 1665*f*

Right adrenalectomy

- laparoscopic, 2415–2416, 2417*f*–2418*f*, 2418
- open, 2413, 2413*f*

Right colon pouches

- with intussuscepted terminal ileum, 3219–3220
- operative technique variations for, 3228, 3229*f*

Rigid cystourethroscopes, 186, 188*f*–189*f*, 188*t*

Rigid lithotripters, 2111–2112

Rigid metal dilators, 171, 171*f*

RIVUR study, Randomized Intervention for Management of Vesicoureteral Reflux (RIVUR) study

RJF, Relative jet frequency

R-LESS, Robotic laparoscopic single-site surgery

RMS, Rhabdomyosarcoma

RNA

- in transcription, 1346.e3, 1346.e3*f*
- in translation, 1346.e3, 1346.e3*f*–1346.e4*f*

Robot-assisted adrenalectomy, 2418–2419, 2419*f*–2420*f*, 2422–2423

Robot-assisted approach, incorporation of, in minimally invasive urinary diversion, 3258, 3258*b*

Robot-assisted intracorporeal continent cutaneous diversion, 3269–3270, 3269*f*, 3270*b*

Robotic inguinal lymphadenectomy, for penile cancer, 1761, 1794

- background of, 1794
- surgical technique for, 1761

Robotic laparoscopic single-site surgery (R-LESS), for kidney surgery, 2306

Robotic machine failure, in robotic prostatectomy, 3580

Robotic partial nephrectomy, 811–813, 814*f*

Robotic port site incisions, 459*f*

Robotic prostatectomy, open prostatectomy *versus*, 3532

Robotic radical cystectomy, 3143–3157, 3159*b*

- anterior vascular pedicle dissection, 3148, 3149*f*–3150*f*
- extended pelvic lymphadenectomy, 3148–3152
- instrumentation of, 3146, 3146*t*
- lateral space of Retzius, 3148, 3149*f*–3150*f*
- patient positioning of, 3145, 3145*f*
- patient selection of, 3144–3145
- port and assistant placement of, 3145–3146, 3145*f*
- posterior dissection of, 3146, 3146*t*, 3147*f*–3148*f*

- reoperation after, 3270–3273
- sigmoid release of, 3146, 3146*t*, 3147*f*
- ureteral control and posterior pedicle dissection, 3152–3157, 3155*f*–3156*f*

Robotic surgery, 203
- access technology for
  - hand-assist devices, 212
  - LESS devices, 212, 212.e2*f*
  - trocars, 211, 211*f*, 212.e2*f*
- complications and troubleshooting in, 223–231, 232*b*
  - anesthesia-related, 228
  - early postoperative, 230–231
  - equipment-related, 223–231
  - exit-related, 230
  - late postoperative, 231
  - during learning curve, 223
  - pneumoperitoneum-related, 224
  - seminal vesicle surgery, 1864
- equipment placement for, 205–207, 205.e1*f*
- instrumentation used in
  - abdomen exit, 218–219
  - for da Vinci Robotic System, 218, 218*f*
  - for grasping and blunt dissection, 218
  - for incising and hemostasis, 215–216, 215.e3*f*
  - for LESS, 218
  - for morcellation, 218
  - for NOTES, 218
  - for port site closure, 219
  - for retraction, 218
  - for specimen entrapment, 217–218, 217*f*
  - for stapling and clipping, 216–217
  - surgical pharmaceuticals, 215
  - for suturing and tissue anastomosis, 215–216
- operative team placement for
  - retroperitoneal upper abdominal procedures, 207, 207*f*
  - transperitoneal and extraperitoneal pelvic procedures, 207
  - transperitoneal upper abdominal procedures, 206.e1*f*, 207.e1*f*
- physiologic considerations in, 223*b*
  - hemodynamic effects related to approach and patient position, 222
  - hormonal and metabolic effects during surgery, 222–223
  - immunologic effects, 223
  - insufflant choice, 220
  - pneumoperitoneum pressure choice, 220

- preoperative preparation for, 204*b*
  - blood products, 204
  - bowel preparation, 204
  - operating room setup, 205, 205*b*
  - patient positioning, 205, 205*f*
  - patient selection and contraindications, 203–204
  - prophylaxis, 205
- procedure for, 219*b*
  - abdomen exit, 218–219
  - hand-assist device placement, 212
  - port removal and fascial closure, 218–219
  - port site closure, 219
  - pre-incision checklist, 207
  - skin closure, 219
  - trocar placement, 212–213
- training and practicing for, 231–233, 233*b*
  - equipment for, 232
  - formal programs for, 233
- ureteral injuries with, 1993

Robotic systems, 206, 206.e1*f*

Robotic-assisted laparoscopic partial nephrectomy (RaLPN), 2300

Robotic-assisted laparoscopic radical prostatectomy (RALRP)

- complications of, 3580, 3583*b*
- evolution of, 3566
- outcomes of, 3579–3580, 3583*b*
  - oncologic, 3583
- pure laparoscopic *versus*, 3570
- quality-of-life outcomes after, 3581
- technique of, 3578*b*

Robotic-assisted laparoscopic sacrocolpopexy, for apical pelvic organ prolapse repair, 2800–2803, 2801*f*–2803*f*

Robotic-assisted laparoscopic simple prostatectomy, 3454–3455

- abdominal access, insufflation, and trocar placement for, 3454–3455
- adenoma enucleation in, 3455
- adenoma extraction and closure for, 3455
- bladder neck incision for, 3455
- hemostasis and vesicourethral anastomosis, 3455

  - patient positioning for, 3454
  - space of Retzius development for, 3455

Robotic-assisted laparoscopic surgery
  - bladder diverticulectomy, Bladder diverticulectomy
  - Boari flap, Boari flap
  - for kidney, 2282–2284, 2284*f*–2285*f*
  - pyelolithotomy, for pediatric kidney stone disease, 868–870
  - pyeloplasty, for ureteropelvic junction obstruction, 1956
  - pyelopyelostomy, for retrocaval ureter, 1963
  - ureteral reimplantation, Ureteral reimplantation
  - ureteroureterostomy, for ureteral stricture disease, 1972
  - for vesicovaginal fistula, Vesicovaginal fistula

Robotic-assisted pyeloplasty, 832
  - techniques of, 832–834, 833*f*

Robotic-assisted retroperitoneal lymph node dissection, 1734–1741, 1741*b*
  - complications of, 1739–1740, 1739*t*
  - postoperative care for, 1738–1739
  - prospective nerve-sparing techniques for, 1739
  - rationale and evolution of, 1734
  - results and current status for, 1740–1741
  - surgical technique for, 1735–1738
    - port placement and technique, 1738, 1738*f*
    - preoperative patient preparation and technical considerations for, 1735

Roentgen, Wilhelm Conrad, 3587

Rolipram, for ureteral relaxation, 1899

Rome IV criteria, for functional constipation in children, 474, 474*t*, 475*f*

RON, in UTUC, 2198

Rosebud stoma, 3182, 3182*f*–3183*f*

Round ligament, 2430, 2431*f*

RPLND, Retroperitoneal lymph node dissection

RPTs, Retroperitoneal tumors

RRP, Retropubic radical prostatectomy

RSD, Reflex sympathetic dystrophy

RSPO1 gene, 992*f*, 992*t*, 993

RSR, Relative saturation ratio

RTA, Renal tubular acidosis

RTE, Real-time elastography

RTK, Rhabdoid tumor of kidney

RUF, Rectourethral fistulae

S

S phase, deregulation of progression through, in GU cancers, 1347.e1

S phase arrest, deregulation of, in GU cancers, 1347.e2

Saccules, 2967

SACD, Subacute combined degeneration

Sacral agenesis, 487, 641–644, 644*b*
- pathogenesis of, 642–643
- presentation of, 641–642, 643*f*–644*f*
- specific recommendations for, 643–644

Sacral arteries, 2451–2452, 2451*t*

Sacral dorsal rhizotomy, 2741–2742, 2742*f*
- clinical results of, 2743, 2744*t*
- goal and effect of, 2742–2743
- patient selection in, 2742
- surgical implantation technique of, 2742–2743, 2743*f*

Sacral evoked response: bulbocavernosus reflex latency, 1527

Sacral nerve stimulation (SNS), 2510, 2752–2754
- current indications for, 2752
- implantation procedure for, 2753–2754
  - percutaneous nerve evaluation test, 2754
  - staged implant procedure, 2754, 2754*f*
- indications for, 2753, 2753*f*

  - for nonobstructive chronic underactive bladder, 2753
  - for OAB with or without urinary continence, 2752–2753
  - outcomes for, 2752
  - patient selection for, 2753–2754

- Sacral neuromodulation (SNM), 2739
  - for detrusor underactivity, 2662
  - for neuromuscular dysfunction of lower urinary tract, 637–638
  - for OAB, 2647
  - for UUI, 2546
- Sacral plexus, 2433
  - neuromodulation of, 2510
- Sacral spinal cord injury
  - lower urinary tract dysfunction with, 2611–2612, 2613*f*
  - management with, 2613*b*
- Sacrococcygeal teratoma, lower urinary tract dysfunction and, 2631
- Sacrocolpopexy, abdominal, for apical pelvic organ prolapse repair, 2798–2809
  - complications of, 2804, 2806*t*
  - cost of, 2809
  - laparoscopic
    - comparison with, 2806, 2807*t*
    - *versus* robotic-assisted, 2806–2809, 2808*t*
    - *versus* robotic-assisted colpopexy, 2809
    - technique for, 2802*f*–2803*f*, 2803–2804
  - learning curve in, 2809
  - open, technique for, 2798–2800, 2800*f*–2801*f*
  - results of, 2804–2806, 2805*t*
  - robotic-assisted laparoscopic, 2800–2803, 2801*f*–2803*f*, 2810*t*–2811*t*
- Sacrohysteropexy
  - minimally invasive, 2822–2823, 2824*t*
  - open abdominal, 2822–2823, 2824*t*
  - results with, 2823
- Sacroiliac ligaments, 2428–2429
- Sacrospinous ligament colposuspension, 2433

Sacrospinous ligament fixation (SSLF), for pelvic organ prolapse repair, 2793–2797
  - complications with, 2797
  - results of, 2795–2797, 2796*t*–2797*t*
  - surgical anatomy for, 2794–2795, 2795*f*
  - technique for, 2795, 2796*f*

Sacrospinous ligaments, 2428–2429

Sacrotuberous ligaments, 2428–2429

Sacrum, 2427, 2428*f*, 2444

Salbutamol, to facilitate bladder filling and urine storage, 2682*t*

Saline drop test examination, for bowel injury, 276

Salvage brachytherapy, for biochemical recurrence after radiation therapy, 3668

Salvage cryotherapy, for biochemical recurrence after radiation therapy, 3667–3668, 3669*t*

Salvage high-intensity focused ultrasound, for biochemical recurrence after radiation therapy, 3668

Salvage radiation therapy, for biochemical recurrence after radical prostatectomy, 3662–3663
  - adjuvant radiation therapy *versus*, 3664–3665
  - androgen deprivation therapy (ADT), 3663–3664
  - dose response, 3663
  - whole-pelvis *versus* prostatic bed radiation therapy, 3664, 3664*f*–3665*f*

Salvage radical prostatectomy, for biochemical recurrence after radiation therapy, 3667, 3667*t*

Salvage robotic-assisted radical prostatectomy, 3583–3584
  - technique of, 3584

Salvage RPLND, 1727–1728, 1728*t*

Sansert, Methysergide

Saphenous hiatus, 1791

Sarcoidosis

  - hypercalcemia in, 2020
  - hypercalciuria in, 2050

Sarcomas
  - of bladder
    - adenocarcinoma, 3090, 3090*f*
    - small cell carcinoma, 3089, 3089*f*
    - squamous cell cancer, 3089–3090, 3089*f*
    - urachal adenocarcinoma, 3090, 3090*b*
  - of kidney, 2180–2181, 2181*t*, 2182*f*
  - of prostate, 3512
  - of testicular adnexa, 1709

Sarcomatoid differentiation, in RCC, 2149*t*–2151*t*, 2155, 2155*f*

Saw palmetto berry, for benign prostatic hyperplasia, 3395–3398, 3396*f*, 3397*t*

Scabies
  - infestation, 1295–1296, 1297*f*
  - as STD, 1271

Scalpels, for laparoscopic and robotic surgery, 214

Scandinavian Prostate Cancer Group Study Number 4 (SPCG-4), 3529–3530, 3539

Scanning electron microscope (SEM)
  - of bladder blood vessels, 2464*f*
  - of urothelium, 2462, 2463*f*

Scardino-Prince vertical flap, for ureteropelvic junction obstruction, 1961, 1962*f*

Scarpa fascia, 2444, 2446*f*

Scattering, of ultrasound waves, 71, 71*f*

SCC, Squamous cell carcinoma

SCCis, Squamous cell carcinoma in situ

SCD, Sickle cell disease

Scheduled voiding regimens, Toileting programs

Schistosomal myelopathy, lower urinary tract dysfunction and, 2626

Schistosomiasis

  - in bladder tumor, 3077
  - of genitourinary tract, 1319–1328, 1328*b*
    - biology and life cycle, 1319, 1320*f*–1321*f*
    - diagnosis, 1325–1326, 1325*f*–1326*f*
    - epidemiology, 1319–1321, 1321–1324, 1321*f*, 1323*f*
    - history, 1319
    - prevention and control, 1327–1328
    - prognosis, 1327
    - treatment, 1326–1327
      - surgical management in, 1327

Schizophrenia, lower urinary tract dysfunction and, 2630

Schrott-Erlangen approach, for classic bladder exstrophy, 545
  - continence outcomes with, 560

Schwannomas
  - intrarenal, 2132
  - in retroperitoneum, 2235

SCI, Spinal cord injury

Sciatic nerve injury, 261–262

Scintillation crystal, 91

Scissors, for laparoscopic and robotic surgery, 214

Scleroderma, lower urinary tract dysfunction and, 2631

Sclerosing lymphangitis, 1302–1304

Sclerotherapy, 903, 903.e1*f*, 1845–1847, 1848*t*

Screening tests, for genitourinary tuberculosis, 1310–1311

Scrotal agenesis, 887, 887.e1*f*

Scrotal anomalies, 886–888
  - bifid scrotum, 886, 887*f*
  - ectopic scrotum, 886–887, 888*f*
  - scrotal agenesis, 887, 887.e1*f*
  - scrotal hypoplasia, 887
  - scrotoschisis, 887–888, 888.e1*f*

Scrotal elephantiasis, as filariasis clinical manifestation, 1330, 1330*f*

Scrotal engulfment, 885–886, 886*f*

Scrotal hydrocele, 889

Scrotal incision, in urologic surgery, 142–143

Scrotal mass, 392

- in neonate, 387, 387*t*

Scrotal pain, patient history of, 2

Scrotal reconstruction, 3054, 3054.e1*f*

Scrotal ultrasonography, for pediatric urology, 389

Scrotal wall, 1843

Scrotectomy, 1844–1845, 1846*f*

Scrotoplasty, 941, 3068

Scrotum, 1843

- access into, 1844
- acute, Acute scrotum
- anatomy of, 1389*b*, 1843, 1844*f*
  - arterial supply, 1387–1389
  - gross structure, 1387–1389, 1388*f*
  - lymphatic drainage, 1389
  - nerve supply, 1389
  - venous drainage, 1389
- in genitourinary tuberculosis, 1309
- penetrating injuries to, 3051
- physical examination for, 11, 11*f*
- surgeries of, 1843–1864
  - approaches to, 1844, 1850*b*, 1855*b*
  - complications of, 1855–1856
  - innervation, 1843
  - preoperative considerations of, 1843–1844
  - reconstruction, 1845, 1847*f*
  - vasectomy, Vasectomy
- ultrasonography of, 81–84, 1373
  - for GCTs, 1685–1686, 1685*f*
  - indications for, 82
  - normal findings in, 82–83, 83*f*–85*f*
  - procedural applications of, 83

    - sonoelastography, 84
    - technique of, 82

SCSTs, Sex cord-stromal tumors

SDHRCC, Succinate dehydrogenase RCC

Sealants, for laparoscopic and robotic surgery, 215.e2

Seborrheic dermatitis (SD), as papulosquamous disorder, 1282–1283

Seborrheic keratosis, 1304, 1305*f*

Second malignancies
- after bladder RMS treatment, 1117
- after Wilms tumor treatment, 1108

Second messengers, in ureteral contractions, 1885–1887, 1885*f*–1886*f*

Secondary cryptorchidism, 949

Secondary cutaneous lesions, 1273, 1274*t*

Secondary hyperoxaluria, 858–859

Secondary paraureteral diverticula, 525

Secondary syphilis, 1257, 1258*f*

Secondary therapy, receipt of, 105

Secondary vestibulodynia, 1651

Second-look nephroscopy, in antegrade nephroureteroscopic, for UTUC, 2217

Sedation, 484

Segmental hypoplasia, 744, 744*f*

Segmental nephrectomy, for large renal tumors, 2263–2264, 2263.e1*f*–2263.e2*f*, 2264.e1*f*, 2265*f*

Segmental pyelonephritis, 388–389

Segmental ureteral resection, for UTUC, 2207–2210
- ileal ureteral replacement, 2208, 2209*f*
- laparoscopic or robotic distal ureterectomy and reimplantation, 2208, 2209*t*
- open segmental ureterectomy, 2207, 2208*f*–2209*f*
- results of, 2208–2210

SELECT, Selenium and Vitamin E Cancer Prevention Trial

Selective α_1-blockers, 3356–3357

Selective androgen receptor modulators, for benign prostatic hyperplasia, 3377

Selective estrogen receptor modulators (SERMs), for benign prostatic hyperplasia, 3377

Selective serotonin reuptake inhibitors, and PE, 1571–1572

Selective tissue estrogenic activity regulator, for female sexual arousal disorders, 1649–1650

SelectMDx test, 3486

Selenium, in prostate cancer prevention, 3476, 3476*f*

Selenium and Vitamin E Cancer Prevention Trial (SELECT), 3476, 3476*f*

Self-care practices, for bowel function, 2734

Self-catheterization, orthotopic urinary diversion and, 3238

Self-styled dilators, for achieving extraperitoneal access and developing extraperitoneal space, 210

SEM, Scanning electron microscope

Semen
  coagulation and liquefaction of, 3303, 3304*b*
  density of, 896–897
  evaluation of, in male infertility, 1438–1442
    acrosome reaction, 1442
    bulk semen parameters, 1438–1440, 1438*t*
    comet assay, 1441–1442
    computer-assisted semen analysis, 1440.e2
    denatured sperm DNA assays, 1442
    pyospermia assays, 1440–1441
    reactive oxygen species, 1442
    secondary semen assays, 1440–1441
    semen volume, 1439
    sperm density, 1439
    sperm DNA integrity assays, 1441
    sperm fluorescence in situ hybridization, 1442
    sperm morphology, 1439–1440
    sperm motility, 1439
    sperm mucus interaction, 1442
    sperm ovum interaction, 1442
    sperm ultrastructural assessment, 1442
    sperm vitality, 1440
    tertiary and investigational sperm assays, 1441–1442
    TUNEL assay, 1441, 1441*f*
Semenogelins I and II, in prostatic secretions, 3298*t*, 3300
Seminal vesicle and ejaculatory ducts, physiology of, 1407–1408, 1408*b*
  gross architecture and cytoarchitecture, 1407
  unit function, 1407
Seminal vesicle cysts (SVCs), management of, 1862–1863
Seminal vesicle invasion, 3511
Seminal vesicle secretory proteins, in prostatic secretions of, 3303
Seminal vesicles
  anatomy of, 1378*b*, 1856, 1856*f*–1858*f*
    arterial supply, 1377
    gross structure, 1377
    lymphatic drainage, 1378
    microanatomic architecture, 1377
    nerve supply, 1378

        - venous drainage, 1378
    - development of, 3280
    - dissection of, in laparoscopic radical prostatectomy, 3573–3574, 3574*f*
    - embryology of, 1856, 1856*f*–1858*f*
    - in genitourinary tuberculosis, 1309
    - HIV and, 1266
    - imaging
        - CT, 1378
        - MRI, 1378, 1378*f*
        - transrectal ultrasound, 1378
    - in retropubic radical prostatectomy, excision of, 3559–3560, 3560*f*–3561*f*
    - surgeries of, 1843–1864, 1863*b*
        - anterior approach to, 1856–1857, 1859*f*–1861*f*
        - complications of, 1863–1864
        - perineal approach to, 1857
        - posterior approach to, 1857–1862, 1862*f*
        - preoperative considerations of, 1843–1844
        - scrotal wall procedures, 1844–1845
        - testis, 1845–1850
        - transrectal ultrasound-guided aspiration, 1863
        - transurethral endoscopic treatments, 1863
        - tumor excision, 1863
- Seminiferous epithelium, 1445.e1, 1445.e2*f*
- Seminiferous tubules, 1370, 1371*f*, 1373, 1393, 1393*f*, 1396–1398
- Seminomas, 1680, 1702–1706, 1706*b*
    - genomic alterations in, 1353, 1361
    - histology of, 1682, 1683*f*
    - treatment of, 1692, 1692*b*
        - clinical stage I tumors, 1702–1704
        - clinical stage IIA and IIB tumors, 1704–1705
        - clinical stage IIC and III tumors, 1705–1706
        - relapsed tumors, 1706
    - treatment of, RPLND, 1731–1732
- Seminomatous GCTs, 2227
- Semirigid ureteroscopes, 192, 192*f*, 193*t*
    - care and sterilization of, 195–197
    - technique for, 199–201, 201*f*

Senior-Loken syndrome, 756

Sensate focus, for female orgasmic disorder, 1647

Sensation, bladder
  altered, filling/storage failure due to, 2517–2518
  detrusor underactivity and, 2659
  terminology for, 2581

Sensorineural deafness, 347

Sensor-transducer function, of bladder urothelium, 2469–2470

Sensory innervation, in ureteral function, 1889

Sensory nerve (afferent) signaling, in overactive bladder, 2640

Sentinel lymph node biopsy
  of inguinal nodes, for penile cancer, 1760
  for penile cancer, 1792–1793

Sepsis
  with intestinal anastomoses, 3180
  UTIs and, 1182–1187, 1183*b*–1184*b*

Septic shock, UTIs and, 1182–1187, 1184*b*

Serenoa repens (saw palmetto berry), for benign prostatic hyperplasia, 3395–3398, 3396*f*, 3397*t*

Serlopitant, to facilitate bladder filling and urine storage, 2713.e4

Serology, syphilis tests, 1258

Seromuscular enterocystoplasty, 705–706, 705*f*

Serotonin (5-HT)
  in ED, 1494, 1495*t*
  in efferent pathways to bladder, 2488–2489
  in ejaculatory response, 1564
  urethral function effects of, 1902

Serotonin-noradrenaline uptake inhibitors, for stress urinary incontinence in women, 2714–2716

Serotonin-receptor effectors, 1534

Serous-lined extramural tunnel, for orthotopic urinary diversion, 3244–3245, 3245*f*

Sertoli cell tumors, 1124, 1708

Sertoli cell-only syndrome, 1445.e1, 1445.e1*f*

Sertoli cells, 1392, 1437

- testis physiology and, 1396–1398, 1397*f*

Serum gonadotropin measurements, 1528

Serum laboratory studies, in urine, 25

Serum prolactin measurement, 1528

Serum testosterone measurements, 1527–1528

Serum tests, for UTIs, 438

Serum thyroid function tests, 1528–1529

Severe bilateral urinary tract dilation, considerations for, 371

Sex cord-stromal tumors (SCSTs), 1707–1708

- retroperitoneal tumors and, 2229
- treatment of, RPLND, 1732–1733

Sex determination, 1392

Sex hormone-binding globulin, 1434, 1436–1437, 1437*b*

Sex reassignment surgery (SRS), 3062

Sex steroids, lower urinary tract and, 2502–2503

Sextant biopsy, of prostate, 3497

Sexual activity

- benign prostatic hyperplasia and, 3322, 3322*f*, 3323*t*
- prostate cancer and, 3463–3464

Sexual development, 990–997

- disorders of, Disorders of sex development
- gender identity, role, and orientation, 996–997
- gonadal function, 994–995, 994*b*
    - ovary, 995

      - testis, 994, 995*f*
  - gonadal stage of differentiation, 993–994, 994*f*, 994*b*
  - normal genotypic development, 990–993
    - additional genes in, 991–993, 992*f*, 992*t*
    - chromosomal sex, 990, 991*f*, 991*b*
    - SRY, 990, 991*f*–992*f*
  - normal phenotypic development, 993–994
  - phenotypic, 995–996, 995*f*–997*f*
  - psychosexual development, 996–997, 997*b*

Sexual dysfunction, Erectile dysfunction
  - after mid-urethral slings, 2873
  - after transurethral needle ablation of prostate, 3433
  - benign prostatic hyperplasia and, 3378
  - of female
    - arousal dysfunction, 1636
    - definitions of, 1635, 1637*b*
    - DSM-5 definitions of, 1635–1636, 1635*t*
    - epidemiology, 1636–1637, 1637*b*
    - female sexual interest-arousal disorder, 1635–1636
    - genital-pelvic pain dysfunction, 1636
    - genito-pelvic pain-penetration disorder, 1636
    - hypoactive sexual desire dysfunction, 1636
    - hypohedonic orgasm, 1636
    - orgasmic disorder, 1636
    - painful orgasm, 1636
    - persistent genital arousal disorder, 1636
    - postcoital syndrome, 1636
    - sexual arousal dysfunction, 1636
  - hormonal therapy and, 3681
  - patient history of, 6
  - prostatitis and, 1210

Sexual function
  - α1-adrenergic blockers and, 3370
  - of female
    - evaluation of sexual wellness, 1627–1637
    - female sexual physiology, 1627.e4
    - female sexual response, 1627.e4–1627.e5, 1627.e4*f*
    - international consultation on sexual medicine, 1636
    - mental aspects of sexual response, 1627.e6
    - physiologic measures of, 1634, 1634*t*

        - PLISSIT model for, 1628–1629, 1628*t*–1629*t*
        - in special populations, 1637–1640, 1640*b*
            - fertility in transgender people, 1638–1639
            - gender dysphoria and hormonal treatment, 1638, 1639*t*
            - in LGBTQ, 1637–1638, 1638*t*
            - malignancies in female transgender patients, 1639–1640
            - sexuality and disability, 1640
    - localized prostate cancer and, 3524–3525
    - pelvic organ prolapse and, 2593
    - in prune-belly syndrome, 600
    - transurethral microwave therapy and, 3430

Sexual health, in elderly, 2920–2921

Sexual Health Inventory for Men (SHIM), 112*t*

Sexual history, and male infertility, 1433–1434

Sexual intercourse, penile fracture with, 3048

Sexual maturation, 1390

Sexual Quality of Life for Men (SQOL-M), 112*t*

Sexual relations, patient history of, 9

Sexual wellness in women, evaluation of, 1627–1637, 1635*b*
- history, 1627–1629, 1628*t*–1630*t*
- laboratory tests for, 1633–1634
- partner, 1629
- physical examination in, 1629–1633, 1632*f*–1633*f*
- questionnaires for, 1629, 1630*t*–1632*t*

Sexuality
- with exstrophy-epispadias complex
    - female concerns, 566–567
    - male concerns, 565–566
- neural tube defects and, 629–631

Sexually transmitted diseases (STDs), 1251–1272, 1272*b*
- CDC screening recommendations for, 1251–1252
- cutaneous infections and infestations from, 1288, 1289*f*
- epidemiology of, 1251–1252, 1252*t*
- epididymitis, 1255
- genital ulcers, 1255–1261, 1255*t*

  - chancroid, 1255*t*, 1259–1260, 1259*f*
  - diagnosis of, 1256
  - granuloma inguinale, 1260
  - herpes, 1255*t*
  - HPV, 1261, 1262*f*
  - lymphogranuloma, 1255*t*, 1260–1261, 1260*f*
  - *Molluscum contagiosum*, 1261, 1261*f*
  - pediculosis pubis, 1271
  - presentation of, 1256, 1256*f*
  - scabies, 1271
  - syphilis, 1255*t*, 1257, 1257*f*–1258*f*, 1257*t*
  - treatment of, 1256–1257, 1256*t*
  - vaginitis, 1271–1272, 1272*t*
- gonococcal infections, 1252
- HIV, 1264–1268
  - diagnosis, 1264
  - erectile dysfunction and, 1267
  - interactions with other STDs, 1257, 1264–1268
  - Kaposi sarcoma, 1267–1268
  - male circumcision, 1264
  - malignancy, 1267
  - nephrolithiasis, 1266
  - non-AIDS-defining urologic malignancies, 1268
  - nonulcerating skin infections and, 1265
  - postexposure prophylaxis, 1264–1265
  - pre-exposure prophylaxis, 1265
  - prostatitis and, 1266
  - renal dysfunction and, 1266–1267
  - renal infections, 1266
  - testis, epididymis, seminal vesicles and, 1266
  - urologic manifestations of, 1265–1268, 1265*f*
  - UTI and, 1265–1266
  - voiding dysfunction and, 1267
- nongonococcal urethritis, 1253, 1254*f*
  - chlamydia, 1253
  - *Mycoplasma genitalium*, 1253–1254
  - recurrent and persistent, 1254
  - *Trichomonas vaginalis*, 1254
- prostate cancer and, 3463–3464
- reportable, 1252
- urethritis, 1252–1254
- viral hepatitis and, 1268–1271, 1269*t*
- Zika virus, 1263–1264

Shared decision making, in localized prostate cancer, 3525

Sharp dissectors, for laparoscopic and robotic surgery, 214

Shear stress mechanism, of stone fragmentation, 2097

Shear wave elastography (SWE), 74, 76*f*

Shock wave lithotripsy (SWL), 2094–2103, 2103*b*

- adjuncts to improve, 2102, 2102*b*
- attenuation values and, 2077.e2
- bioeffects of, 2097–2100
  - acute renal injury as, 2098–2099, 2098*f*–2099*f*, 2099*b*
  - chronic renal injury as, 2099–2100, 2099*t*
  - extrarenal damage as, 2097–2098, 2097*f*
- combination of ultrasonography and fluoroscopy for, 2095
- contraindications to, 2072*b*
- extracorporeal, 2069.e2–2069.e3
- factors negatively affecting success of, 2072*b*
- fluoroscopy for, 2094–2095
- future direction in, 2102–2103, 2103*f*
- generator types for, 2094
  - electrohydraulic (spark gap), 2094, 2095*f*
  - electromagnetic, 2094, 2095*f*
  - piezoelectric, 2094, 2096*f*
- imaging systems for, 2094–2095
- methods and physical principles, 2094–2097
- morbid obesity and, 2089
- old age and frailty and, 2089–2090
- optimization of, 2100–2102, 2100*b*, 2101*f*, 2102*b*
- pediatric, 864–865, 865*b*
  - limitations and concerns with, 865
  - stone size, location, and composition, 864–865
  - technique for, 865
- prior renal surgery and, 2090
- for renal calculi
  - in calyceal diverticula, 2078
  - in horseshoe kidneys, 2079
  - lower pole calculi, 2081, 2081*f*, 2082*t*, 2083*f*
  - in renal ectopia, 2081
  - stone composition and, 2076, 2076*f*

        - stone localization and, 2075
    - renal function and, 2088–2089
    - renal transplants and, 2091
    - solitary kidney and, 2089
    - spinal deformity or limb contractures and, 2090
    - for staghorn calculi, 2074
    - stone burden and
        - between 1 to 2 cm, 2073
        - greater than 2 cm, 2074
        - up to 1 cm, 2072
    - stone fragmentation in, 2095–2097, 2096*f*
    - tissue injury from, 2100
    - ultrasonography for, 2095
    - uncorrected coagulopathy and, 2090
    - for ureteral calculi
        - duplicated collecting system and, 2087
        - in megaureter, 2087
        - outcome of, 2091
        - stone burden and, 2087
        - stone composition and, 2087
        - stone localization and, 2085–2086, 2086*t*
        - with ureteral stricture or stenosis, 2087–2088
    - urinary diversion and, 2091
    - urinary tract infection and, 2088
- ShockPulse-SE, 245–246
- Short bowel, urinary intestinal diversion and, 3203
- Short Screening Instrument for Psychological Problems in Enuresis (SSIPPE), 477
- Shunting, for ischemic priapism, 1554–1558, 1555*f*–1559*f*, 1556*b*
- Shy-Drager syndrome, lower urinary tract dysfunction with, 2606
- Sickle cell disease (SCD), 451
    - and priapism, 1544, 1547*b*
- Sickle cell trait and disease, contrast media and, 32
- Siderophore aerobactin, 429
- Sigma-rectum pouch, 3210–3211

Sigmoid colon, colon conduit and, 3196, 3197*f*, 3198*t*

Sigmoid cystoplasty, 694–695, 696*f*

Sigmoid kidney, 728*f*, 729

Sigmoid pouch, for orthotopic urinary diversion, 3248, 3249*f*

Signal transduction cascade, 429, 430*f*

Signal transmission, in urodynamic studies, 2558

Sildenafil (Viagra)

- to facilitate bladder filling and urine storage, 2682*t*, 2701
- for ureteral relaxation, 1899

Silicate stones, 2033

Silicone catheters, 152

Silicone microimplants (Macroplastique), 2894, 2894*f*

- for female urinary incontinence, 2894
- of male stress urinary incontinence, 2897

Silk suture, 150–151

Silodosin

- for benign prostatic hyperplasia, 3365, 3365*f*, 3366*t*
- to facilitate bladder emptying, 2720.e1
- to facilitate bladder filling and urine storage, 2682*t*
- ureteral response to, 1888

SILS Port, 212.e1, 212.e1*f*

Silver nitrate, for BPS/IC treatment, 1244.e1

Simple cysts, 766–770, 770*b*

- classification of, 768–770, 769*b*, 770*f*
- clinical features of, 766
- evaluation of, 768, 768*f*–769*f*
- histopathology of, 766–768
- prognosis of, 770, 770*f*
- treatment of, 770, 770*f*

Simple nephrectomy

- laparoscopic, 2285–2291
    - dissection of ureter, 2287, 2287*f*
    - identification of renal hilum, 2287–2288, 2288*f*
    - organ entrapment and extraction, 2289, 2289*f*–2290*f*
    - postoperative management for, 2289
    - reflection of colon, 2285–2286, 2287*f*
    - results of, 2291
    - securing of renal blood vessels, 2288, 2288*f*
    - upper pole dissection, 2288, 2288*f*
- open, 2253–2254, 2253.e2*f*, 2254*f*

Simple orchiectomy, 1848
- technique of, 1848, 1849*f*

Simple prostatectomy, nocturia and, 2671–2673

Simple renal ectopia, anomalies of, 723–724, 724*f*–725*f*
- description for, 723–724
- diagnosis of, 724
- incidence of, 723
- prognosis of, 724

Sims-Huhner test, 1442.e2

Simulation, 3587–3588

Single-incision mid-urethral slings
- anatomy of, 2851
- complications of, 2863–2866
- outcomes for, 2857–2858
- surgical approach to, 2854, 2855*f*

Single-lumen catheters, 154

Single-photon emission computed tomography (SPECT), 91, 440

Single photon imaging
- physical characteristics of, 92*t*
- principles of, 91
- three-dimensional images in, 91

Sinovaginal bulbs, 325–326, 776

Sipuleucel-T, 1341, 3697–3698, 3697*f*

Skeletal muscle, smooth muscles compared with, 2471*t*

Skeletal system abnormalities, with cloacal exstrophy, 575

Skene gland, cysts of, urethral diverticula differentiated from, 2974, 2986*f*

Skin, of external genitalia, loss of, 3053–3054, 3053*f*–3054*f*

Skin bridge, of penis, 874–875, 874*f*

Skin closure, 150–151

- after laparoscopic and robotic surgery, 219

Skin tag, 1304

Skin tags

- hymenal, 978–979, 979*f*

SLE, Systemic lupus erythematosus

Sleep

- enuresis and, 662
- nocturia effect on, 2664–2665
- states of, 2665

Sleep efficiency, definition of, 2664–2665

Sleep latency, definition of, 2664–2665

Slings, 2830–2876

- alternative treatment options to, 2833
- evolution of, 2830–2831, 2832*b*
- mid-urethral, Midurethral sling
- for pelvic organ prolapse, anterior compartment, 2788–2790, 2789*f*
- preoperative assessment for, 2832–2833, 2833*b*
- pubovaginal, Pubovaginal sling
- for urinary incontinence, in geriatric patients, 2920.e5

Slitlike adjusted Mathieu (SLAM) procedure, 924, 925*f*

Slow-twitch fibers

- male sphincteric mechanisms and, 2594
- of urethral striated muscle, 2467

Slow-wave sleep (SWS), glucose homeostasis and, 2665–2666

SMA, Superior mesenteric artery

Small bowel, for urinary diversion, 3160

Small bowel anastomosis

- tunneled, 3188
- in urinary diversion, 3187–3189
  - Bricker anastomosis, 3187, 3187*f*
  - Hammock anastomosis, 3189
  - Le Duc technique, 3189, 3189*f*
  - split-nipple technique, 3188–3189, 3188*f*
  - tunneled, 3188, 3188*f*
  - ureteral dipping technique, 3189
  - ureteral-small bowel, 3189, 3190*f*
  - Wallace technique, 3187–3188, 3188*f*

Small cell carcinoma

- of bladder, 3089, 3089*f*
- of kidney, 2181*t*, 2183

Small cell neuroendocrine prostate cancer, 3693

Smegma pearl, 393–394

Smegmoma, 393–394, 393*f*

Smoking

- benign prostatic hyperplasia and, 3324
- in bladder tumor, 3076
- and ED, 1509
- penile cancer and, 1744
- prostate cancer and, 3464, 3543
- urinary incontinence and, 2586
- UTUC risk and, 2186

Smooth muscles

- in benign prostatic hyperplasia, 3315, 3315*f*
- of bladder, 2465, 2465*f*
  - actinomyosin cross-bridge cycling, 2472–2473, 2472*b*, 2473*f*
  - action potentials of, 2473–2474, 2474*f*
  - calcium signaling in, 2475–2476, 2476*f*
  - contractile proteins, 2470–2472, 2471*f*–2473*f*
  - electrical response propagation, 2476–2477, 2477*f*

    - excitation-contraction coupling in, 2474–2475, 2475*f*
    - during filling, 2478
    - interstitial cells of, 2477–2478, 2478*f*
    - membrane electrical properties of, 2473–2474, 2474*f*
    - motor sensory network in, 2479–2480, 2479*f*
    - physiology of, 2470–2478, 2478*b*
    - during voiding, 2479
  - of penis, physiology of, 1495–1500
    - cytosolic calcium, and calcium sensitization pathway, 1495
    - intracavernous tissue architecture and erectile response, 1500, 1501*t*
    - modulation of antitumescence pathways by protumescence pathways, 1496–1500
    - molecular pathways that directly modulate intracellular free calcium and, 1495
    - molecular pathways that indirectly modulate intracellular free calcium and, 1495–1496
  - skeletal muscle compared with, 2471*t*
  - of urethral sphincter, 2467
    - CVA and, 2603

Smooth sphincter, decreasing outlet resistance at, to facilitate bladder emptying, 2719–2720

Smooth sphincter dyssynergia, 2521–2522
  - with autonomic dysreflexia, 2614

SMV, Superior mesenteric vein

SNM, Sacral neuromodulation

SNS, Sacral nerve stimulation

Social history, 8–9

Social Security Administration (SSA), 102

Society for Fetal Urology classification, 404, 405*f*

Society for Fetal Urology grading system, 360–361, 360*f*

Socioeconomic factors, in benign prostatic hyperplasia, 3321, 3321*t*

Sodium
  - filtrate transport, 1906–1909, 1907*f*–1910*f*, 1909*b*
  - fractional excretion of, urinary tract obstruction and, 777
  - hypercalciuria and, 2051
  - in kidney, of neonate, 342, 342*b*
  - in pediatric kidney stone disease, 869

    - transport of, urinary tract obstruction and, 793
- Sodium cellulose phosphate, for hypercalciuria, 2053
- Sodium pentosan polysulfate, for BPS/IC oral therapy, 1242
- Soft tissue sarcomas, in retroperitoneum, 2229
- Solid retroperitoneal tumors, cystic change of, retroperitoneal tumors and, 2238
- Solid/cystic renal masses, 384–385
- Solifenacin
  - for diminished bladder, 2668–2669, 2675*t*–2677*t*
  - to facilitate bladder filling and urine storage, 2682, 2682*t*
    - with β-adrenoreceptor antagonists, 2700
- Solitary fibrous tumor
  - of kidney, 2132
  - retroperitoneal tumors and, 2232, 2233*f*
- Solitary multilocular cyst nephroma, in pediatric patients, 1109
- Solubility product, 2009–2010, 2010*f*
- Solutes, filtrate transport, 1912–1913
- Somatic nervous system
  - and ED, 1527
  - in retroperitoneum, 1675–1679, 1675.e1*f*, 1677*f*–1678*f*, 1679*t*
- Somatic pathways
  - of lower urinary tract, 2480*f*–2481*f*, 2481
  - penile erection and, 1490–1491
- Sonic Hedgehog protein, ED and, 1506
- Sonoelastography
  - limitations of, 84, 85*f*
  - mode of, 74–75
  - of scrotum, 84
- Sonography, 403, 405*b*
  - prenatal, 404, 407*f*
- Sorafenib, 1358

    - for RCC, 2179*t*–2180*t*, 2334, 2334*t*

South African star grass, for benign prostatic hyperplasia, 3398

Southwest Oncology Group (SWOG), 3691, 3692*f*

SOX9 gene, 992*f*, 992*t*, 993, 3276

Soy, in prostate cancer prevention, 3476

Space of Retzius, 2850

- development of
  - for laparoscopic radical prostatectomy, 3571–3572, 3572*f*
  - of open simple prostatectomy, 3450
  - of robot-assisted laparoscopic simple prostatectomy, 3455

Spall fracture mechanism, of stone fragmentation, 2095–2096

Spallation, of stone fragmentation, 2095–2096

SPARTAN trial, 3696

Spatial compounding ultrasonography, 74

Specialist nurse, in transitional urology, 1046–1047

Specific gravity, of urine, 15

Specimen collection, for urinalysis, 14

Specimen entrapment instrumentation, for laparoscopic and robotic surgery, 217–218, 217*f*

Speckling, in ultrasonography, 71, 72*f*

SPECT, Single-photon emission computed tomography

Sperm cryopreservation, for TGCT patients, 1690

Sperm granuloma, complication of scrotal surgery, 1856

Sperm production, age-related decrease in, 1392

Sperm retrieval

- in anejaculation, 1580
- surgical techniques for, 1472–1476, 1473*t*
  - microsurgical epididymal sperm aspiration, 1473–1474, 1473*f*–1474*f*
  - percutaneous epididymal sperm aspiration, 1474, 1474*f*
  - postmortem, 1476

        - testicular sperm extraction, 1474–1475, 1474*f*–1475*f*, 1475*t*

Spermatic cord, 1393

Spermatic cord dissection, patient positioning and port placement for, 1736, 1736*f*, 1738

Spermatic cord torsion, 893–897

- acute intravaginal, 893–894
    - clinical presentation of, 894
    - diagnostic studies of, 894, 895*f*
    - management and surgical treatment of, 894–896, 896*f*
    - predisposing factors for, 893–894
    - prognosis for, 896–897
- extravaginal, 897, 897*f*
- intermittent intravaginal, 897

Spermatic vessel ligation, for prune-belly syndrome, 594

Spermatids, 1398, 1398*f*

Spermatoceles, excision of, 1850

Spermatocytes, 1396, 1397*f*–1398*f*, 1400–1401

Spermatocytic tumors, histology of, 1682

Spermatogenesis, 1399–1402

- cycle of, 1399, 1399*f*
- genetics of, 1401
    - paternal age and, 1401–1402, 1402*b*
- germ cells in, 1396, 1401
- meiosis, 1401
- Sertoli cells in, 1396, 1401
- spermiogenesis, 1401
- testis stem cell migration, 1399
- testis stem cell proliferation, 1400
- testis stem cell renewal, 1400, 1400*f*

Spermatogonia, 1396

Spermatotoxicity, 1429–1432

- medications and
    - antibiotics, 1430

    - antihypertensives, 1430
    - anti-inflammatory agents, 1431
    - antipsychotics, 1430
    - cytotoxic chemotherapeutics, 1430–1431
    - endocrine modulators, 1429
    - environmental toxicants, 1431
    - opioids, 1430
    - phosphodiesterase V inhibitors, 1431
    - radiation, 1431–1432
    - recreational drugs, 1430
    - thermal toxicity, 1431

Spermatozoa, 1408–1410, 1409*f*, 1410*b*
  - epididymal function and, 1404–1406
    - maturation, 1404–1405
    - storage of, 1404
    - transport of, 1404
  - maturation of
    - biochemical changes, 1405
    - fertility, 1405, 1405*f*
    - motility, 1404–1405, 1405*f*
  - production of, Spermatogenesis
  - vas deferens function and, 1406–1407

Sphincteric urinary incontinence
  - cause of, 2993
  - classification of, 2993–2998
  - diagnosis of, 2995–2998
  - etiology of, 2993–2998
  - evaluation of, 2995–2998, 2996*f*, 2998*b*
    - cystoscopy for, 2996–2997, 2997*f*
    - history for, 2995
    - laboratory of, 2996
    - patient-reported measures, 2995–2996
    - physical examination for, 2996
    - urodynamics for, 2997
  - history and development of devices, 2993–2994, 2994*f*
  - implantation device technique, 3000–3005
    - artificial urinary sphincter, 3000, 3001*f*, 3003*f*
    - four-arm sling, 3005, 3005*b*
    - operative preparation of, 3000
    - transobturator bulbourethral sling, 3005, 3006*f*

- improving quality of evidence, 3009
- indications for surgery, 2998–2999, 2999*b*
- innovations and emerging concepts in device design, 2994–2995
- mechanisms of continence with surgical devices, 2995
- pathophysiology of, 2993–2998
- training paradigms of, 3009

Spina bifida (SB)

- kidney size with, 629
- lower urinary tract dysfunction with, 2617
- neuropathic bladder, 1052–1053
    - changes in function and continence, 1052
    - preparation for pregnancy, 1052–1053
    - renal and urologic concerns, 1052
    - sex and sexuality, 1052

Spinal cord

- abnormalities of, with cloacal exstrophy, 574–575
- cystitis and, chemical changes with, 2507
- neuromuscular lower urinary tract dysfunction involvement of, 2607–2619
- segment numbering for, 2609

Spinal cord compression, neuroblastoma causing, 1096

Spinal cord injury (SCI)

- bladder calculi in patients with, 2116–2117
- cystitis with, 2467
- and delayed ejaculation, 1576–1577, 1576*t*
- epidemiology of, 2609, 2609*b*
- general concepts of, 2609, 2609*b*
- with high-pressure bladders, host defense mechanisms in UTIs and, 1140
- lower urinary tract dysfunction with, 2609–2617, 2609*b*
    - autonomic dysreflexia, 2614–2615
    - bladder cancer and, 2616
    - follow-up for, 2616–2617
    - neurologic and urodynamic correlation, 2612–2614
    - sacral, 2611–2612, 2613*f*, 2613*b*
    - spinal shock, 2610
    - suprasacral, 2610–2611, 2611*f*–2612*f*, 2612*b*
    - urinary tract infection, 2615
    - vesicoureteral reflux, 2615

        - in women, 2615–2616
    - morbidity of, 2609, 2609*b*
    - neurogenic detrusor overactivity and, 2504–2505
    - traumatic, 648–649, 650*b*
        - pathogenesis of, 648
        - presentation of, 648, 648*f*
        - specific recommendations for, 649
    - urothelium and, 2467

Spinal cord pathways, in lower urinary tract, 2481–2482, 2481*t*, 2482*f*

Spinal defects, in bladder exstrophy, 531–532

Spinal dysraphism, 487
- lower urinary tract dysfunction with, 2617–2619
- occult, 644, 645*t*

Spinal shock, lower urinary tract dysfunction with, 2610

Spinal stenosis, lower urinary tract dysfunction with, 2620

Spinal ultrasound, 389

Spindle assembly checkpoint, deregulation of, 1347.e3

Spine, anatomy of, in retroperitoneum, 1658, 1658.e1*f*

Splenic injury
- during laparoscopic and robotic surgery, 230.e1
- during radical nephrectomy, 2261

Splenogonadal fusion, 963, 963*f*

Splenorenal ligament, 1865

Split onlay skin flap (SOS) hypospadias repair technique, 946*f*

Split symphysis variant of exstrophy-epispadias complex, 538

Split-and-roll technique, for RPLND, 2239, 2239*f*

Split-nipple technique, in urinary diversion, 3188–3189, 3188*f*

Split-thickness skin grafts, for urethral and penile reconstruction, 1805

SPOP mutations, in prostate cancer, 3470–3472

Sporadic glomerulocystic kidney disease (GCKD), 772

Sporadic prostate cancer, 1355–1358

Spread-out Bragg peak, 3594, 3594*f*

Squamous cell carcinoma (SCC)

- of bladder, 3089–3090, 3089*f*
  - in pediatric patients, 1118
- as neoplastic condition, 1296, 1299*f*
- of penis, 1743–1751
  - biopsy for, 1746, 1747*b*
  - delay in, 1745
  - diagnosis of, 1745–1751
  - differential diagnosis of, 1751
  - etiology of, 1743–1744, 1745*b*
  - examination for, 1745–1746
  - histologic features of, 1746, 1747*b*
  - invasive, 1743
  - invasive carcinoma, 1743
  - laboratory studies of, 1746–1747
  - natural history of, 1745, 1746*b*
  - presentation of, 1745, 1746*b*
  - prevention of, 1744, 1745*b*
  - radiologic studies of, 1747–1748, 1748*b*
  - signs of, 1745
  - staging of, 1748–1751, 1748*t*–1749*t*, 1750*f*, 1751*t*, 1751*b*
  - symptoms of, 1745
- of upper urinary tract, 2189

Squamous cell carcinoma in situ (SCCis), as neoplastic condition, 1296, 1298*f*

Squeezing-splitting mechanism, of stone fragmentation, 2096–2097

SRY gene, 990, 991*f*–992*f*, 1392

SSIGN score, Stage, Size, Grade and Necrosis (SSIGN) score

SSIPPE, Short Screening Instrument for Psychological Problems in Enuresis

SSIs, Surgical site infections

SSLF, Sacrospinous ligament fixation

Stab wounds

- renal, 1982
  - nonoperative management of, 1986–1987
- ureteral, 1995–1996

diagnosis of, 1995–1996

Staccato-shaped curve, 480

Stage, Size, Grade and Necrosis (SSIGN) score, 2162

Staged implant procedure, for sacral neuromodulation, 2754

Staged tubularized autograft (STAG) repair, 927, 930*f*

Staghorn calculi, 2070, 2070*f*

- epidemiology of, 2031
- percutaneous nephrolithotomy and, 2106
- surgical treatment selection for, 2074–2075

Stamey incontinence grading system, 2893*t*

Stamey needles, in pubovaginal sling placement, 2838–2839

Standardized uptake value (SUV), 91

Stapled sigmoid reservoir, for cutaneous continent urinary diversion, 3228, 3230*f*

Staplers, 466

Stapling devices, for laparoscopic and robotic surgery, 216, 216*f*

StAR, Steroid acute regulatory protein

Starr plication technique, for megaureter in children, 851, 851*f*

States of saturation, renal calculi and, 2009–2010, 2010*f*–2011*f*

Static cystography, 39, 40*f*

Statins

- and ED, 1509
- for metabolic syndrome, 1422
- for prostate cancer, 3544–3545
- in prostate cancer prevention, 3475

Stauffer syndrome, 2156

STDs, Sexually transmitted diseases

Stem cell transplantation, for RCC, 2331, 2331*t*

Stem cells

- in GU cancers, 1367, 1368*b*

- in prostate cancer, 3466, 3468*f*
- testis
  - migration of, 1399
  - proliferation of, 1400
  - renewal of, 1400, 1400*f*

Stenosis, urethral, reconstructive surgery for, 1811

Stents
- endovascular, for renovascular injuries, 1990
- for prostate, 3443–3444
- ureteral, Ureteral stents
- for ureteroenteric strictures, 1977
- for ureteropelvic junction obstruction, 834–835
  - in percutaneous antegrade endopyelotomy, 1948
- for urethral stricture disease, 1818–1819

Stepper, 3592

Stereotactic body radiation therapy, 3593–3594

Sterilization, of ureteroscopes, 195–197

Steroid acute regulatory protein (StAR), 1394–1395
- deficiency of, 1011

Steroid hormones, of male reproductive system, 1390, 1391*f*

Steroid-dependent nephrotic syndrome (SDNS), 345

Steroidogenic dysfunction, 1447

Steroid-resistant nephrotic syndrome (SRNS), 345

Steroids
- for retroperitoneal fibrosis, 1980
- sex, lower urinary tract and, 2502–2503

Steroid-sensitive nephrotic syndrome (SSNS), and nephrotic syndrome, 345

Stevens-Johnson syndrome, 1277–1278, 1278*f*

Stimulated myoplasty, 2903

Stoma
- for intestinal anastomoses in urinary intestinal diversion, 3161*f*

        - complications of, 3180*t*
        - flush, 3182–3183
        - loop end ileostomy, 3183, 3183*f*
        - nipple (rosebud), 3182, 3182*f*–3183*f*
    - in minimally invasive urinary diversion, preparation of, 3262, 3262*b*

Stomach
    - selection, 3162
    - for urinary diversion, 3160

Stone breakage mechanism, of stone fragmentation, 2097

Stone clearance, 861

Stone composition, after shock wave lithotripsy, 865

Stone disease, Calculi

Stone fragility, 2077.e1–2077.e2

Stone location, after shock wave lithotripsy, 865

Stone removal
    - laparoscopic and robotic, 2113
    - in percutaneous nephrolithotomy, 2104–2105

Stone retrieval devices, for ureteroscopic, intraluminal lithotripsy, 198

Stone size, after shock wave lithotripsy, 864–865

Stones, Calculi

Stop test, 2659

“Straddle fractures,” urethral injuries with, 3057, 3057.e1*f*

Straight ureteral catheter, 166.e1*f*

Streak gonad, 321–322, 323*f*

Stress Incontinence Surgical Treatment Efficacy Trial (SISTEr), 2840–2841

Stress relaxation, ureteral, 1885, 1885*f*

Stress strategies, 2725, 2725.e1*t*

Stress urinary incontinence (SUI)
    - adrenergic agonists for, 2501
    - with bipolar transurethral resection of prostate, 3419

  - BMI and, 2540–2541
  - cause of, 2834
  - definition of, 2539, 2581
  - estrogens for, 2713–2714
  - female
    - algorithm for management of, 2760*f*
    - drugs used for treatment of, 2713–2716
    - urodynamic studies, evidence-based review in, 2574–2576
    - use of injectable agents for, 2890–2891
  - genuine, 2518
  - hypermobility in, 2757, 2834
  - male
    - drugs used for treatment for, 2716
    - injectable agents for, 2896–2897
      - after urinary diversion, 2897–2898
      - injection techniques, 2896–2897
  - mechanisms of, 2504
  - occult, urodynamic studies of, 2563
  - pathophysiology of, 2517, 2596–2597, 2597*b*
    - intrinsic sphincteric deficiency in, 2597, 2757, 2834, 2859–2860
    - urethral support and, loss of, 2596–2597, 2596*f*
  - patient history of, 4
  - pelvic floor muscle training for, 2540, 2723
  - recurrent, midurethral sling outcomes for, 2860–2861, 2861*b*
  - treatment for
    - choice of, 2757
    - in men, 2546–2547, 2546*t*, 2547*b*
    - midurethral sling, Midurethral sling
    - pharmacologic, 2683*t*, 2713, 2717*b*
    - pubovaginal sling for, Pubovaginal sling
    - surgical, 2574
  - urethral collagen and, 2467
  - urethral slings for, 2831
- Striated muscles, of urethral sphincter, 2466–2467
  - fiber types of, 2466–2467
- Striated sphincter, decreasing outlet resistance at, to facilitate bladder emptying, 2720
- Striated sphincter dyssynergia, 2521–2522

  after CVA, 2603
  baclofen for, 2720.e2–2720.e3
  with cerebellar ataxia, 2604
  cystourethrogram of, 2611*f*
  with MS, 2608
  with suprasacral spinal cord injury, 2610
  with traumatic brain injury, 2604

Striated urethral sphincter, surgical anatomy of, 3549, 3549*f*–3550*f*

Strickler technique, in urinary diversion, 3186, 3186*t*, 3187*f*

Stricture
  ureteral, Ureteral strictures
  with ureterointestinal anastomoses, in urinary intestinal diversion, 3192
  in ureteroscopic stone management, 2108
  urethral, Urethral strictures

Stroke
  and ED, 1502
  lower urinary tract dysfunction and, 2602–2603

Stroma
  of bladder wall, 2463
  of prostate, 3280
  of urethra, 2468

Stromal-epithelial interactions
  in benign prostatic hyperplasia, 3309
  in prostate growth, 3287

Structural chromosomal anomalies, male infertility and, 1446

Structural sperm abnormalities, in male infertility, 1451–1452

Structure, definition of, 101

Studer neobladder, modified, for minimally invasive urinary diversion, 3263*t*, 3264–3265

Studer pouch, for orthotopic urinary diversion, 3245, 3247*f*

Subacute combined degeneration (SACD), lower urinary tract dysfunction and, 2619

Subclinical Cushing syndrome, 2363–2364

Subclinical filariasis, 1329

Subcostal artery, 136*f*

Subcostal flank approach, for open kidney surgery, 2249–2250, 2249.e1*f*, 2250*f*–2251*f*, 2250.e1*f*

Subcutaneous emphysema, during laparoscopic and robotic surgery, 225

Subcutaneous tissue expansion, for hypospadias, 945

Subepithelial plexus, 2463

Submucosal stone, in ureteroscopic stone management, 2109

Substance P, in ureteral function, 1889

Suburethral hammock, 2831

Suburethral slings, 2830

Suburothelial interstitial cells, 2470, 2470*f*

Succinate dehydrogenase RCC (SDHRCC), 2142*t*, 2144

Sudeck's point, 3161

SUI, Stress urinary incontinence

Sunitinib, 3700
- for RCC, 2179*t*–2180*t*, 2334–2335, 2335*t*, 2336*f*

Superficial bladder cancer, Non-muscle-invasive bladder cancer

Superficial fascia, 136*f*

Superficial inguinal lymph node dissection, for penile cancer, 1761, 1793–1794

Superficial perineal space, 1807.e10

Superior ectopic kidney, 728*f*, 729–731
- anomalies of, 729–730, 730*f*
- diagnosis of, 730–731
- prognosis of, 731
- symptoms of, 730, 730*f*

Superior lumbar triangle, 169

Superior mesenteric artery (SMA), 1869–1870

- in radical nephrectomy, 2261

Superior mesenteric vein (SMV), in radical nephrectomy, 2261

Superior vesical artery, 1377

Supernumerary kidney, 721–722, 722*f*–723*f*

Supernumerary renal arteries, 1869

Supine hypotensive syndrome, in pregnant, 282

Supine position, 146, 165

- modifications to, 165

Suplatast tosilate, for BPS/IC oral therapy, 1241*t*, 1243

Supracostal flank approach, for open kidney surgery, 2250–2251, 2251.e1*f*

Supradiaphragmatic tumors, testicular tumors with, 1720

Suprapubic aspiration, 437

- in urine collection, 1141

Suprapubic catheterization, 155–156

- techniques of, 156
    - placement with a guidewire and Seldinger technique, 156

Suprapubic cystostomy, 190–191

- for posterior urethral injury, 3058, 3058*f*

Suprapubic simple prostatectomy, 3452–3454

- adenoma enucleation for, 3453, 3453*f*
- closure for, 3453–3454, 3454*f*
- hemostatic maneuvers for, 3452*f*, 3453
- prostate exposure for, 3452–3453, 3452*f*

Suprasacral spinal cord injury

- lower urinary tract dysfunction with, 2610–2611, 2611*f*–2612*f*
- management with, 2612*b*

Supraspinal pathways, in lower urinary tract, 2493–2497

- additional regions in, 2496–2497

    - bladder modulatory mechanisms, 2493–2494, 2495*f*
    - brain-bladder control model, 2497, 2498*f*
    - central circuitry regulation of, 2494–2495
    - cerebral control of voiding, 2496
    - human brain imaging studies in, 2496, 2496*f*
    - modulators in, 2495–2496
    - neurotransmitters in, 2495–2496
    - pontine micturition center, 2493–2494, 2495*f*
- Supravesical urinary diversion, for prune-belly syndrome, 591–592
- Surface electrode electromyography (sEMG), for PFM activity measurement, 2729
- Surgery
    - adrenal, Adrenal surgery
    - in ED, 1537
    - for genito-pelvic pain-penetration disorder, 1653, 1653.e1*f*
    - for hypospadias
        - Byars flap, 927, 931*f*
        - distal, 918
        - general considerations of, 916–918, 918*b*
        - graft or flap, 932, 934*f*
        - one-stage, 925–926
        - preputial flaps, 926*f*, 938–939
        - proximal, 925–932, 925*b*
        - scrotoplasty, 941
        - technical aspects of, 925–926, 926*f*
        - two-stage, 926–927
        - two-stage, with free graft, 927, 929*f*
        - two-stage, with pedicle flap, 927–932, 931*f*
    - kidney, Kidney surgery
    - for Peyronie's disease (PD), 1616–1625, 1626*b*
        - indications, 1610*f*, 1616–1618, 1618*b*, 1619*t*
        - penile prosthesis, 1624–1625
        - tunica lengthening procedures, 1621–1624
        - tunical shortening procedures, 1618–1621, 1620*f*–1621*f*, 1622*t*
    - postoperative care for, Postoperative care
    - preoperative care for, Preoperative care
    - preparation for, 123–125
        - antithrombotic therapy, 32–34

        bowel preparation, 124–125
        medication management, 32
Surgery-specific cardiac risk, 120
Surgical antimicrobial prophylaxis, in pediatric kidney stone disease, 861
Surgical castration, 3371
Surgical history, adrenal surgery and, 2407–2408
Surgical landmarks, of adrenal glands, 2345, 2347*f*–2348*f*, 2405–2406, 2406*f*
Surgical mesh removal, 2885–2886, 2886*b*
Surgical neurotomy, cryoablation, and neuromodulation, of dorsal penile nerve, 1572.e3
Surgical outcomes, assessment of, 101–114
Surgical pharmaceuticals, for laparoscopic and robotic surgery, 215
Surgical site infections (SSIs), 453–454
    risk of, 145
Surgical wounds
    classification of, 1201*t*
    of radical nephrectomy, closure of, 2261
Surgiflo, 148
Surveillance
    active, for RCC, 2173, 2173*t*
    for NSGCTs, 1693–1694, 1694*t*
    for penile cancer, 1757
    for seminomas, 1703–1704, 1703*t*
Suturing instrumentation, for laparoscopic and robotic surgery, 215–216, 216*f*
SWE, Shear wave elastography
Swedish Reflux Study, 515
SWL, Shock wave lithotripsy
Swyer syndrome, 998*t*, 1004–1005, 1005*f*
Sympathetic ganglia tumors, retroperitoneal tumors and, 2234–2235, 2235*f*

Sympathetic nervous system
  in retroperitoneum, 1675
  in ureteral function, 1888–1889
Sympathetic pathways, of lower urinary tract, 2480, 2480*f*
Sympathetic transmission, in neural control of LUT, 2593
Sympathomimetic agents, for neuromuscular dysfunction of lower urinary tract, 634, 634*f*
Symptom Impact Index (SII), 111*t*
Symptom Severity Index (SSI), 111*t*
Symptomatic microscopic hematuria, 252
Symptoms Management After Reducing Therapy (SMART) trial, 3389
Syndrome of complete androgen insensitivity, 1013–1014
Syndrome of partial androgen resistance, 1014
Syndromic cryptorchidism, 957–958
SYNERGY study, 3702
Synovial sarcoma, retroperitoneal tumors and, 2231–2232, 2232*f*
Synthetic mesh, for posterior compartment repair, 2829
Synthetic prosthetic materials, for pubovaginal sling, 2835, 2836*t*
  outcomes of, 2843
Syphilis
  diagnosis, 1258–1259
  as genital ulcers, 1255*t*, 1257, 1257*f*–1258*f*, 1257*t*
  treatment, 1259, 1259*t*
Syringomyelia, lower urinary tract dysfunction and, 2626
Systemic chemotherapy, for UTUC, 2222
Systemic lupus erythematosus (SLE), lower urinary tract dysfunction and, 2626
Systemic sclerosis, lower urinary tract dysfunction and, 2631
Systemic therapies, for retroperitoneal tumors, 2245–2247

T

T pouch

  for orthotopic urinary diversion, 3245–3246, 3247*f*

  with valved rectum, 3209–3210, 3210*f*

T2-weighted imaging, 63, 63*f*

Tabes dorsalis, lower urinary tract dysfunction with, 2619

Tachykinins

  lower urinary tract and, 2501–2502, 2501*t*

  in ureteral function, 1889

Tadalafil

  for benign prostatic hyperplasia, 3385

  to facilitate bladder filling and urine storage, 2682*t*, 2701

  for ureteral relaxation, 1899

  for urinary incontinence, 2544–2546

Tamm-Horsfall protein

  in crystal formation, 2014

  in crystal matrix, 2015

Tamoxifen, for PD, 1611, 1616*t*

Tamsulosin

  for benign prostatic hyperplasia, 3363–3365, 3363*f*, 3364*t*

  for detrusor underactivity, 2661

  for diminished bladder capacity, 2675*t*–2677*t*

  to facilitate bladder emptying, 2720.e1

  to facilitate bladder filling and urine storage, 2682*t*

    with antimuscarinic agent, 2704

  for nocturia, 2671–2673

  ureteral response to, 1888

Tanner classification, 871, 872*t*

“Taqaandan,” penile fracture with, 3048

Targeted angioembolization, for renal tumors, 2323

Targeted molecular therapies, for advanced RCC

  basis of, 2332–2333, 2333*f*
  combination and sequential therapy with, 2339–2341
  immune “checkpoint” inhibitor-based combination strategies, 2341, 2342*f*
  mTOR pathway inhibitors, 2326–2327, 2338–2339, 2340*f*, 2340*t*
  VEGFR-based, 2326–2327, 2333–2337, 2333*t*–2335*t*, 2336*f*, 2337*t*
Tasquinimod, 3700–3701
TAX 327 study, 3691, 3691*f*
TCC, Transitional cell carcinoma
^{99m}Tc-DMSA, Technetium-99m dimercaptosuccinic acid
^{99m}TC-DTPA, TECHNETIUM-99M-DIETHYLENETRIAMINE PENTAACETIC ACID
^{99m}Tc-MAG3, Technetium-99m-mercaptoacetyl triglycine
TCS, Tethered cord syndrome
^{99m}Tc-sestamibi, 98, 98*f*
Tea, UTUC risk and, 2186
Technetium-99m (^{99}mTc), 91, 92*t*
Technetium-99m dimercaptosuccinic acid (^{99m}Tc-DMSA), 92, 96*b*
  for imaging infections of kidney, 96
  renal cortical imaging with, 95–96
Technetium-^{99m}-diethylenetriamine pentaacetic acid (^{99m}Tc-DTPA), 41, 92, 96*b*
  dynamic renal scintigraphy with, 94–95
  scintigraphy, 94–95
Technetium-99m-mercaptoacetyl triglycine (^{99m}Tc-MAG3), 41, 41*f*, 92, 94*f*, 96*b*
  additional applications of, 94–95
  dynamic renal imaging with, 92–93
  dynamic renal scintigraphy with, 94–95
  renogram, 95*f*
Telomerase, in GU cancers, 1362–1365, 1363*f*, 1365*b*
  chromosome stabilizing activity of, 1364
  as potential diagnostic marker, 1364
  therapies based on, 1365

Telomere shortening, 2905

Telomeres, in GU cancers, 1362–1365, 1365*b*

  cancers and premalignant lesions with short, 1363–1364

  chromosomal instability and, 1362

  prostate cancer prognosis using, 1364–1365

  as tumor suppressive mechanism, 1363, 1363*f*

Temperature, epididymal function and, 1406

Temporal lobe epilepsy, and ED, 1502

Temsirolimus (Torisel), 2148

  for RCC, 2338–2339, 2339*t*–2340*t*, 2340*f*

Tension-free vaginal tape (TVT) procedure

  colposuspension compared with, 2773–2774

  evolution of, 2831

Teratomas, 1122

  histology of, 1683*f*, 1684

  PC-RPLND findings of, survival outcomes associated with, 1726, 1727*t*

Terazosin

  for autonomic dysreflexia, 2615

  for benign prostatic hyperplasia, 3357–3359, 3357*t*–3358*t*, 3359*f*

  for diminished bladder, 2674, 2675*t*–2677*t*

  to facilitate bladder emptying, 2682*t*, 2720.e1

Terbutaline, to facilitate bladder filling and urine storage, 2682*t*, 2714

Terminal ileum, right colon pouches with intussuscepted, 3219–3220

Tertiary or late syphilis, 1258

Testicular adnexa, tumors of, 1709

Testicular anomalies, cryptorchidism and, 963–964

Testicular artery, 1370–1371, 1372*f*–1373*f*, 1375

Testicular cancer, Paratesticular cancer

  and delayed ejaculation, 1576

  genomic alterations in, 1361–1362

    - gene rearrangements, 1353
  - in geriatric patients, 2920.e13
  - non-germ cell, 1707–1709
    - adenocarcinoma of rete testis, 1708
    - dermoid and epidermoid cysts, 1708
    - secondary metastases, 1709
    - sex cord-stromal tumors, 1707–1708
  - in nuclear medicine, 43–44, 44*f*
  - pediatric, 1121–1125, 1125*b*
    - biomarkers for, 1122, 1122*f*
    - epidemiology of, 1121
    - gonadal stromal tumors, 1124, 1124*f*
    - leukemia and lymphoma metastases, 1124–1125
    - management algorithms for, 1125, 1125*f*
    - microlithiasis, 1124–1125
    - pathogenesis and molecular biology of, 1121
    - presentation of, 1121–1122
    - sexual development disorders associated with, 1122–1124, 1123*t*
    - staging of, 1122, 1122*t*
    - testis-sparing surgery technique for, 1125
    - ultrasonography of, 1122
  - staging of, 1687*t*–1688*t*
- Testicular dysgenesis syndrome (TDS), 909, 955–956
- Testicular fixation, with suture, 1855
- Testicular formation, 317–318, 319*f*, 320*t*

Testicular germ cell tumors (TGCTs), 1680–1707, 1681*t*, 1684*b*, 1688*b*
- clinical staging of, 1687*t*–1688*t*, 1689–1690, 1691*b*
  - chest imaging and, 1690
  - imaging studies, 1689
  - prognostic classification of advanced germ cell tumor, 1690, 1691*t*
  - serum tumor markers in, 1690
  - sperm cryopreservation, 1690
- diagnosis delay, 1685
- diagnostic testing and initial management of, 1685–1688
  - contralateral testis biopsy, 1688
  - partial orchiectomy, 1686–1688
  - radical inguinal orchiectomy, 1686
  - scrotal ultrasound, 1685–1686, 1685*f*
  - serum tumor markers, 1686
  - for suspected extragonadal GCTs, 1688
- differential diagnosis of, 1685
- epidemiology of, 1680
- genomic alterations in, 1122*t*, 1361
- histologic classification of, 1682–1684
  - choriocarcinoma, 1683–1684, 1683*f*
  - EC, 1682–1683, 1683*f*
  - germ cell tumor neoplasia in situ, 1682
  - seminoma, 1682, 1683*f*
  - spermatocytic tumor, 1682
  - teratoma, 1683*f*, 1684
  - YSTs, 1683*f*, 1684
- initial presentation of, 1684–1685
- pathogenesis and biology of, 1681–1682
- physical examination for, 1685
- risk factors for, 1680–1681
- signs and symptoms of, 1684–1685
- suspected, 1688
- treatment of, 1691–1693
  - brain metastases, 1706–1707, 1707*b*
  - NSGCTs, 1692, 1692*b*
  - relapse after, 1700–1702
  - residual mass management after, 1698–1700, 1698*t*–1699*t*
  - seminomas, 1692, 1692*b*
  - sequelae of, 1707, 1707*b*
  - therapeutic principles, 1691–1692

Testicular hypotrophy, 900–901

Testicular injury

- complications with, 3053
- diagnosis of, 3051–3052, 3052*f*
- etiology of, 3051
- management of, 3052–3053, 3052*f*
- outcome of, 3053

Testicular maldevelopment, cryptorchidism and, 961–964

Testicular microlithiasis, 971–972, 971*f*

- in pediatric patients, 1124–1125

Testicular prosthesis placement, 1848–1850, 1849*f*

Testicular retraction, 949

Testicular rupture, 899

Testicular sperm extraction, 1474–1475, 1474*f*–1475*f*, 1475*t*

Testicular torsion, 387, 391–392, 392*f*, 1432

- perinatal, 897, 897*f*

Testicular tumors, 392–393

- laparoscopic retroperitoneal lymph node dissection, 1734–1741, 1741*b*
  - bilateral, 1738
  - complications of, 1739–1740, 1739*t*
  - duplication of, 1735
  - postoperative care after, 1738–1739
  - prospective nerve-sparing techniques for, 1739
  - rationale and evolution of, 1734
  - results and current status of, 1740–1741, 1740*t*
  - staging, 1734–1735
  - surgical technique for, 1735–1738
- malignant, Testicular cancer
- management of, 1711–1712
- as non-AIDS-defining urologic malignancies, 1268
- robotic-assisted retroperitoneal lymph node dissection, 1734–1741, 1741*b*
  - complications of, 1739–1740, 1739*t*
  - postoperative care for, 1738–1739
  - prospective nerve-sparing techniques for, 1739
  - rationale and evolution of, 1734

- results and current status for, 1740–1741
- surgical technique for, 1735–1738

surgery of, 1711–1733, 1712*b*
- delayed orchiectomy, 1712
- evaluation after, 1712
- in high-risk populations, 1727–1729, 1728*t*, 1729*b*
- histologic findings and survival outcomes of, 1726–1727, 1727*t*, 1727*b*
- history, and physical examination, ultrasonography, and preorchiectomy evaluation, 1711–1712
- outcomes, functional considerations, and complications of, 1729–1731, 1732*b*
- for seminoma, 1731–1732
- for sex cord stromal tumors, 1732–1733

surgical decision making for, 1721–1726, 1726*b*
- adjuvant chemotherapy for primary RPLND, 1724–1726
- in cases of clinical complete remission to induction chemotherapy, 1721–1722, 1722*t*
- template use in PC-RPLND, 1723–1724, 1724*f*, 1725*t*
- template use in primary RLND, 1722–1723, 1723*f*, 1723*t*

Testis

anatomy of, 1374*b*
- arterial supply to, 1370–1371, 1372*f*, 1393
- blood supply of, 1453–1454, 1454*t*
- gross structure, 1370, 1371*f*
- lymphatic supply, 1372, 1373*f*
- microanatomic architecture, 1370, 1371*f*
- nerve supply, 1372–1373
- venous drainage, 1372, 1372*f*–1373*f*

androgen production by, 3281–3282, 3282*f*–3283*f*, 3282*t*

anomalies of, cryptorchidism and, 963–964

appendix, torsion of, 897–898, 898*f*

descent of
- gubernacular development and, 951–952, 952*f*
- regulation of, 952–953

differentiation of, 949–950

embryology of, 949–953

function of, 994, 995*f*

in genitourinary tuberculosis, 1309

HIV and, 1266

hormones of, 950–951, 1391–1392, 1391*f*

imaging of
- magnetic resonance imaging, 1373–1374
- scanning electron micrograph, 1393*f*

      - ultrasound, 1373, 1373*f*–1374*f*
  - inflammation of, Orchitis
  - injuries of, 3051–3053
  - magnetic resonance imaging, 1373–1374
  - neoplasms of, 1680–1710, 1681*t*
  - physiology of, 1392–1394, 1402*b*
    - cytoarchitecture, 1394–1399, 1395*f*–1396*f*
    - gross architecture in, 1392–1394, 1393*f*–1394*f*
    - in HPG axis, 1391–1392, 1391*f*
  - in prune-belly syndrome, 584–585, 585*f*
  - ultrasonography of, 82, 1373, 1373*f*–1374*f*
    - indications for, 82
    - normal findings in, 78*f*, 82–83, 83*f*–84*f*
    - procedural applications of, 83
    - sonoelastography, 84
  - undescended, Cryptorchidism
  - vanishing, 959–960, 960*f*

Testis stem cell

  - migration of, 1399
  - proliferation of, 1400
  - renewal of, 1400, 1400*f*

Testis-sparing surgery

  - for pediatric tumors, 1125
  - for TGCT, 1686–1688

Testosterone

  - aging effects on, 1392
  - biosynthesis disorders of, 1011–1013
  - cycles of, 1396, 1396*f*
  - epididymal function and, 1406
  - for female sexual arousal disorders, 1649–1650
  - for female sexual response, 1627.e5–1627.e6
  - in HPG axis, 1391
  - lower urinary tract and, 2503
  - in prostate cancer, 3466, 3467*f*
  - sources of, 3673
  - synthesis of, 1394–1395, 3280–3281, 3283*f*

control of, 1395–1396

Testosterone therapy, 1529–1532, 1531*t*

- buccal, 1530
- cardiovascular risk of, 1424–1425
- intramuscular, 1530
- for metabolic syndrome, 1422
- oral, 1530
- subcutaneous, 1530
- transdermal, 1530

Tethered cord syndrome (TCS), lower urinary tract dysfunction with, 2618

TGCTs, Testicular germ cell tumors

The Cancer Genome Atlas (TGCA), 3467–3468, 3469*f*

Theophylline, for ureteral relaxation, 1899

Thermal ablative therapies, for RCC, 2171–2173, 2171*f*, 2172*t*

“Thermal dose,”, 3426

Thermal index (TI), in ultrasonography, 78

Thermodynamic solubility product (K_{sp}), 2009

Thiazide-induced hypocitraturia, 2056

Thiazides

- for hypercalciuria, 2051–2052, 2052*t*
- in stone formation, 2033

Thick filaments, 2471, 2471*f*

Thiersch Duplay (TD) repair, 921–922, 923*f*

Thigh pain, in mesh complication, 2881

Thin filaments, 2470–2471

Thiol-containing agents, for pediatric kidney stone disease, 869–870

Thiotepa, for non-muscle-invasive bladder cancer, 3103

Thoracic kidney, 725–727, 726*f*

- anomalies of, 726

- description for, 726
- diagnosis of, 726, 726*f*
- embryology of, 725–726
- incidence of, 725
- prognosis of, 727
- symptoms of, 726

Thoracoabdominal approach
- for kidney surgery, 2251–2252, 2252*f*–2253*f*, 2252.e1*f*
- to open adrenalectomy, 2413–2414, 2413*f*–2414*f*

Thoracoabdominal incision, kidney and retroperitoneum approaches, 136–137

Thoracostomy, 181

Three-dimensional conformal radiotherapy, for prostate cancer, 3587–3588, 3588*f*

Three-dimensional laparoscopic systems, 213

Three-dimensional scanning, in ultrasonography, 75, 77*f*

Three-port catheters, 153

Thrombectomy, vena caval, 2266–2278, 2278*b*
- bypass techniques for, 2275–2276, 2275*f*–2276*f*, 2275.e1*f*, 2276.e1*f*
- IVC filtration and permanent interruption for bland thrombus, 2277
- level I, right-sided tumor technique, 2267–2269, 2267.e1*f*, 2269.e1*f*, 2270*f*
- level II, left-sided tumor technique, 2269–2270, 2269.e1*f*, 2271*f*
- level III-IV
  - combined intra-abdominal and intrathoracic approach, 2274–2275, 2274*f*, 2274.e1*f*
  - intra-abdominal approach technique, 2270–2274, 2271*f*–2274*f*, 2273.e1*f*
- patching, replacing, and interrupting of IVC in, 2276–2277, 2277*f*
- perioperative complications, 2277–2278
- preoperative considerations for, 2266–2267, 2267*t*, 2268*f*–2269*f*

Thromboembolic events, after retropubic radical prostatectomy, 3563

Thulium laser, 3442–3443
- complications with, 3443
  - intraoperative, 3443
  - perioperative, 3443
  - postoperative, 3443

    - concept and introduction for, 3442
    - conclusion for, 3443
    - holmium laser enucleation of prostate *versus*, 3442–3443
    - outcomes with, 3442–3443
        - comparative series, 3442–3443
        - single-cohort series, 3442
    - technique for, 3442
    - transurethral resection of prostate *versus*, 3442

Thulium:YAG (Thu:YAG) laser, 240–241

Thymine, 1346.e1, 1346.e2*f*

Tibial nerve stimulation, for OAB, 2647

Tight junction (TJ) proteins, in bladder urothelium, 2467, 2468*f*

Time activity curve (TAC), 92–93, 93*f*

Timed Up and Go (TUG) test, 2910

Timed voiding, 2730.e1*t*, 2731

Tisseel VH Fibrin Sealant, 215.e2

Tissue adhesives (Bioglue), 148

Tissue anastomosis instrumentation, for laparoscopic and robotic surgery, 215–216

Tissue banking, genomic research on, 3586

Tissue matrix, of prostate, 3280

Tissue transfer, principles of, 1805

Tissue-based biomarkers, 3487–3489

Tissue-based genomics, caveats of, 3543

TMP, Trimethoprim

TMP-SMX, Trimethoprim-sulfamethoxazole

TNF-α, Tumor necrosis factor-α

TNM staging, Tumor, nodes, and metastases (TNM) staging

Tofranil, Imipramine

Toileting programs
  bladder training, 2728*f*, 2730, 2730.e1*t*
  caregiver-administered, challenges of, 2732.e1
  delayed voiding, 2732
  habit training, 2730.e1*t*, 2731
  prompted voiding, 2730.e1*t*, 2731–2732
  timed voiding, 2730.e1*t*, 2731
  understanding, 2730.e1*t*
  for urinary incontinence, 2730–2731
Tolterodine, 2498, 2499*t*
  for diminished bladder, 2674, 2675*t*–2677*t*
  to facilitate bladder filling and urine storage, 2682, 2682*t*
    with α-adrenoreceptor antagonists, 2697–2698
    with other antimuscarinics, 2685
Tonsil clamps, in pubovaginal sling placement, 2838–2839
TOOKAD Soluble, 3632
Top-down approach (TDA), 439
Topical local anesthetics, for PE, 1572
Topical therapy, for genito-pelvic pain-penetration disorder, 1653
Topical thrombin agents, 148
Topiramate, in stone formation, 2033
Toremifene citrate, in prostate cancer prevention, 3475
Torisel, Temsirolimus
Toronto group, 3540
Torsion of appendix testis and epididymis, 897–898
Torulopsis glabrata, 445
Total colpocleisis, for apical pelvic organ prolapse repair
  results with, 2812
  technique for, 2812, 2813*f*
Total laparoscopic technique, in nephroureterectomy, for UTUC, 2202, 2203*f*

Total nephrectomy, for renal injuries, 1991

Total parenteral nutrition (TPN), 122

Total scrotectomy, 1844–1845, 1846*f*

Total urogenital mobilization (TUM), 1033–1034, 1034*f*–1036*f*

Tower-shaped curve, 480

Toxins, to facilitate bladder filling and urine storage, 2682*t*, 2707–2709, 2709*b*

- botulinum toxins, 2707–2709
- capsaicin, 2709
- resiniferatoxin, 2709

TP53

- in apoptosis, 1366
- in GU cancers, 1347.e2, 1347.e2*f*, 1348
- in prostate cancer, 3469
- in Wilms tumor, 1098

TPE, Tropical pulmonary eosinophilia

Tract dilation, 170–172

Tract sealants, 176

Traditional open distal ureterectomy, in UTUC, 2200–2201, 2200*f*–2201*f*

Tramadol

- to facilitate bladder filling and urine storage, 2713.e3–2713.e4
- for PE, 1572.e1

Trans Tasman Radiation Oncology Group (TROG), 3600–3602

Transabdominal pelvic ultrasonography

- indications for, 80
- limitations of, 81
- normal findings in, 80–81, 80*f*, 82*f*
- procedural applications of, 81
- technique of, 80

Transcolonic technique of Goodwin, in urinary diversion, 3185–3186, 3186*f*

Transcription, basics of, 1346.e3, 1346.e3*f*

Transcriptional activation domains, of androgen receptors, 3291–3292, 3291*b*, 3292*f*

Transcutaneous electrostimulation, 2748

- sacral dermatome, 2748
- tibial nerve, 2748

Transducers, in urodynamic studies, 2558

Transection, of ureter, delayed recognition, 2001–2002

Transepithelial resistance (TER), 2467

Transferrin, in prostatic secretions, 3298*t*, 3302

Transforming growth factor-β superfamily, in prostate development, 3276–3277

Transforming growth factor-β1 (TGF-β1)

- and PD, 1605–1606
- in tubulointerstitial fibrosis, 787

Transfusion protocol, massive, 147

Transgender, Transmen, Transwomen

- female-to-male, 1841–1842, 1842*b*
- special urologic considerations in, 3062–3072, 3072*b*
  - early postoperative care of, 3069–3070

Transient receptor potential (TRP) channels

- antagonists of, to facilitate bladder filling and urine storage, 2713.e1
- in bladder afferent pathway, 2485

Transient urinary incontinence

- in geriatric patients, 2919.e1
- with holmium laser enucleation of prostate, 3438

Transient urinary tract dilation, 372–373, 373*f*

Transitional cell carcinoma (TCC), Urothelial cancer

- pediatric, 1117–1118, 1123–1124, 1124*f*
- upper tract and lower tract magnetic resonance imaging for, 61, 62*f*

Transitional urology, 1043–1053

- barriers to, 1045–1047
  - expanding numbers and management of service long-term, 1046

        - importance of specialist nurses, 1046–1047
        - institutional, 1045–1046
        - patients, 1046
        - professional, 1046
    - clinical delivery to, 1047
        - geography, 1047
    - clinical practice:major diagnosis of, 1047–1050, 1050*b*
        - blood tests, 1049
        - exstrophy, 1049–1050
        - flow rates, 1048

    - effects of obstruction on, 1894–1898, 1894*f*–1897*f*
        - physiologic methodologies for, 1897–1898, 1898*f*
    - pathologic processes affecting, 1894–1900, 1894*f*–1899*f*, 1901*f*
    - pregnancy effects on, 1900–1901
    - vesicoureteral reflux and, 1898–1899, 1899*f*

Ureteral injuries, 264–267, 1992–2002
  cause of, 1992–1995
  complications of seminal vesicle surgery, 1864
  diagnosis of, 1995–1996
    hematuria, 1995
    intraoperative recognition, 1995
  external trauma, 1992–1993, 1992*t*
    contusion, 1996
    management for, 1996–1999
  imaging of, 1995–1996
    antegrade ureterography, 1995
    computed tomography, 1995, 1995*f*
    intravenous pyelography, 1995–1996, 1996*f*
    retrograde ureterography, 1995
  incidence and anatomic landmarks, 264–265
  in intraoperative consultation, 300–302
    diagnosis/recognition, 300–301
    grade 1 and 2 injury, 301–302
    grade 3 to 5 distal ureteral injury, 302
    grade 3 to 5 mid-and proximal ureteral injury, 302
    grade 5 injury, 302
    incidence, 300, 300*t*
    management, 301
    mechanisms, 300, 301*t*
    principles of repair, 301
    ureteral catheters, 302
    ureteroscopic avulsion injury, 302
  intraoperative management, 265, 266*f*
  key points of, 2002*f*–2003*f*, 2002*b*
  during laparoscopic and robotic surgery, 230.e1
  lower, 1998–1999
    Boari flap for, 1999, 2000*f*
    partial transection for, 1999
    psoas bladder hitch for, 1998–1999, 1999*f*
    ureteroneocystostomy for, 1998
  management of, 1996–2002, 1996*f*
    damage control, 1999
    general principles of, 1996, 1997*f*
  mechanisms of, 265
  midureteral, 1998

  - with monopolar transurethral resection of prostate, 3417
  - presentation of unrecognized, 265–266
  - in robotic prostatectomy, 3580
  - strictures, 267
  - surgical, 1993–1994, 1999–2002
    - avoidance and detection of, 1993–1994, 1994*f*
    - delayed recognition of, 2001–2002
    - immediate recognition of, 2001
    - ligation, 2000–2001, 2001*f*
    - robotic and laparoscopic, 1993
    - tenuous ureteral blood supply, 1994
    - timing of repair of, 1999–2002
    - with vascular surgery, 1993
  - upper, 1996–1998
    - autotransplantation for, 1997
    - bowel interposition for, 1998, 1998*f*
    - monitoring after repair, 1998
    - nephrectomy for, 1998
    - ureterocalicostomy for, 1997
    - ureteroureterostomy for, 1996–1997, 1997*f*
  - ureteroscopic, 1994–1995, 2002
    - avulsion, 2002
    - perforation, 2002
  - ureterovaginal fistula, 266–267

Ureteral leak, 1937, 1937*b*
  - diagnosis of, 1937
  - treatment of, 1937

Ureteral mobilization, for ureteral reimplantation, 3020–3021, 3021*f*

Ureteral obstruction
  - partial, hemodynamic changes with, 792
  - ureteral stenting for, 795

Ureteral pain, patient history of, 2

Ureteral polyps, with megaureter in children, 835–836

Ureteral reconstruction, for prune-belly syndrome, 592

Ureteral reimplantation, 3019–3026
  - complications with, 3025

- evaluation of, 3019, 3019*f*–3020*f*
- laparoscopic and robotic techniques of, 3023–3024, 3024*f*
- nonrefluxing, 3021–3022, 3022–3025, 3022*f*–3024*f*
- outcomes of, 3025–3026
- postoperative care of, 3025
- refluxing, 3023–3026, 3023*f*
- surgical indications of, 3019, 3019*f*–3020*f*
- surgical technique for, 3020–3021

Ureteral stents
- management of, 1936, 1936*b*
  - diagnosis and treatment of, 1936, 1937*f*
  - prevention of, 1936
  - retained, 1936
  - timing of, 1936
- for pediatric genitourinary trauma, 1071
- for ureteral obstruction, 795
- for ureterovaginal fistula, 2945, 2945*f*

Ureteral stones, 406

Ureteral strictures, 1937–1938, 1937*t*, 1938*b*
- autotransplantation for, 1975
- balloon dilation for
  - antegrade, 1967–1968
  - results with, 1968
  - retrograde, 1966–1967, 1967*f*–1968*f*
- buccal mucosa grafting, 1975
- diagnosis of, 1937–1938
- diagnostic studies of, 1966
- endoureterotomy for, 1968–1969
  - antegrade approach to, 1969
  - combined retrograde and antegrade approach, 1969
  - results with, 1969
  - retrograde ureteroscopic approach to, 1968–1969, 1969*f*
- etiology of, 1965–1966, 1966*b*
- intervention for
  - endourologic, 1966–1969, 1967*f*–1970*f*
  - indications for, 1966
  - surgical, 1969–1975, 1970*t*, 1976*b*

    - management algorithm for, 1969*f*
    - with megaureter in children, 835
    - minimally invasive ileal ureteral substitution for, 1973–1975, 1974*f*
    - psoas hitch, 1972–1973
    - renal descensus for, 1973
    - transureteroureterostomy for, 1973
    - treatment of, 1938, 1938*f*
    - ureteral stent placement for, 1966
    - ureteroneocystostomy for, 1972
    - ureteroscopy for, 191–192
    - ureteroureterostomy for, 1970–1972
        - open approach, 1970–1972, 1971*f*
        - postoperative care, 1972
- Ureteral surgery, for genitourinary tuberculosis treatment, 1317–1318
- Ureteral tapering, 1897–1898
- Ureteral tumors, benign
    - other, 2189
    - papilloma, 2188
    - von Brunn nests, 2188
- Ureteric bud branching, 335*f*, 337–338
- Ureteric fistulae, 2942–2946, 2946*b*
    - diagnosis of, 2943–2946, 2943*f*, 2945*f*
    - etiology of, 2942–2943, 2942*b*
    - management of, 2943–2946, 2943*f*, 2945*f*
    - presentation of, 2942–2943
- Ureterocalicostomy
    - for ureteral injuries, upper, 1997
    - for ureteropelvic junction obstruction
        - laparoscopic and robotic-assisted, 1958
        - for UPJ reconstruction, 1962, 1964*f*
- Ureteroceles, 333, 798–825, Ureteral anomalies
    - anatomic description of, 798–799, 799*f*
    - bladder outlet and, 806–807, 807*f*–808*f*
    - excision of, and common-sheath reimplantation, 813–816, 815*f*–816*f*, 817*b*

- prolapsed, 802, 803*f*, 977, 978*f*
- transurethral incision for, 817–819, 818*f*–819*f*, 819*b*
  - reflux outcomes after, 819
- voiding dysfunction and, 820

Ureterocolonic anastomosis
- in robot-assisted intracorporeal continent cutaneous diversion, 3269
- in urinary diversion, 3185–3187
  - complications of, 3191–3192
    - stricture, 3192
    - urinary fistula, 3191–3192
  - Cordonnier and Nesbit techniques, 3187
  - intestinal antireflux valves, 3189–3191
    - intussuscepted ileal valve, 3189–3190, 3191*f*
    - intussuscepted ileocecal valve, 3189–3190, 3191*f*
  - Leadbetter and Clarke technique, 3185, 3185*f*
  - Pagano technique, 3186–3187, 3187*f*
  - Strickler technique, 3186, 3186*t*, 3187*f*
  - transcolonic technique of Goodwin, 3185–3186, 3186*f*

Ureterocystoneostomy, for prune-belly syndrome, 592

Ureterocystoplasty, 703, 703*f*

Ureteroenteric anastomotic stricture, 1977*b*
- evaluation of, 1976
- incidence and etiology of, 1975–1976
- intervention for
  - endourologic, 1976–1977, 1978*f*
  - initial management and, 1976–1977

Uretero-enteric strictures, 3272

Ureteroileal anastomosis, for minimally invasive urinary diversion, 3262

Ureterointestinal anastomosis, for urinary diversion, 3184–3192
- complications of, pyelonephritis, 3180*t*
- intestinal antireflux valves, nipple valve, 3191, 3192*f*
- small bowel anastomoses, 3187–3189
  - Bricker anastomosis, 3187, 3187*f*
  - Hammock anastomosis, 3189
  - Le Duc technique, 3189, 3189*f*
  - split-nipple technique, 3188–3189, 3188*f*
  - tunneled, 3188, 3188*f*
  - ureteral dipping technique, 3189

- ureteral-small bowel, 3189, 3190*f*
- Wallace technique, 3187–3188, 3188*f*

ureterocolonic anastomoses, 3185–3187

- Cordonnier and Nesbit techniques, 3187
- Leadbetter and Clarke technique, 3185, 3185*f*
- Pagano technique, 3186–3187, 3187*f*
- Strickler technique, 3186, 3186*t*, 3187*f*
- transcolonic technique of Goodwin, 3185–3186, 3186*f*
- ureterocolonic anastomoses, 3185–3187

Ureterolysis, for retroperitoneal fibrosis, outcomes of, 1980

Ureteroneocystostomy

- with a bladder psoas muscle hitch or Boari flap, 2207, 2209*f*
- for ureteral stricture disease, 1972

Ureteronephrectomy, proximal, 2204, 2204*f*

Ureteropelvic junction (UPJ)

- disruption of, for pediatric genitourinary trauma, 1074–1075, 1075*f*
- flap procedures of, 1960–1962
  - Culp-DeWeerd spiral flap, 1960–1961, 1961*f*
  - Foley Y-V plasty, 1960, 1960*f*
  - intubated ureterotomy, 1961–1962, 1963*f*
  - Scardino-Prince vertical flap, 1961, 1962*f*
  - ureterocalicostomy for, 1962, 1964*f*
- injury of, 1992–1993
- surgical exposure to, 1953, 1953*f*–1954*f*
- urine transport and, 1891, 1892*f*

Ureteropelvic junction obstruction (UPJO), 400, 507–508, 509*f*, 1942–1963, 1952*b*

- acquired, 1943
- calicovesicostomy for, laparoscopic, 1960
- congenital, 1942, 1943*f*
- diagnosis of, 1942
- dismembered pyeloplasty, 1952–1953
- flap procedures for, 1960–1962
  - Culp-DeWeerd spiral flap, 1960–1961, 1961*f*
  - Foley Y-V plasty, 1960, 1960*f*
  - intubated ureterotomy, 1961–1962, 1963*f*
  - salvage procedures, 1963

    - Scardino-Prince vertical flap, 1961, 1962*f*
    - ureterocalicostomy for, 1962, 1964*f*
- genitourinary trauma and, 1076, 1076*f*
- interventions for, 1947
    - endourologic management of, 1947, 1952*b*
    - historical notes on, 1951–1952
    - indications for, 1945–1963
    - management of complications for, 1963
    - nephrectomy for, 1946–1947
    - operative, 1951–1953
    - options for, 1947–1950
    - postoperative care for, 1963
- intrinsic, 1942
- nephrolithotomy for, percutaneous antegrade endopyelotomy simultaneous with, 1949
- pathogenesis of, 1942–1943, 1943*f*
- patient presentation and diagnostic studies for, 1943–1945, 1944*f*–1946*f*
- pattern of dilation, 373–374
    - recommendations for, 373–374
- in pediatric patients, 826–852
    - associated anomalies, 826
    - clinical presentation of, 826, 827*f*
    - complications with, 832*f*, 835, 835*f*
    - definition of, 826
    - dismembered pyeloplasty, 828, 828*f*–830*f*
    - endoscopic approach to, 830
    - flank approach to, 829
    - laparoscopic pyeloplasty for, 830–834, 833*f*–834*f*
    - lower pole, 826, 827*f*
    - minimally invasive techniques for, 830–835
    - nondismembered pyeloplasty for, 828–829, 829*f*–831*f*
    - outcomes with, 835
    - posterior lumbotomy for, 829, 832*f*
    - secondary, 826
    - surgical approach to, 829
    - surgical indications for, 826–827
    - surgical repair of, 827–828
- percutaneous antegrade endopyelotomy for, 1947, 1947*f*–1948*f*
    - nephrolithotomy simultaneous with, 1949
- percutaneous endopyeloplasty for, 1949
- postoperative care and complications, 1957
- pyeloplasty for
    - dismembered, 1945–1946, 1953*f*–1954*f*

        - laparoscopic and robotic intervention, 1953–1955, 1960*b*
        - laparoscopic dismembered tubularized flap, 1960
        - open surgery, 1953
        - with pyelolithotomy, 1958–1960
        - salvage procedures for, 1963
    - renal calculi with, surgical management of, 2077
    - results of, 1957–1958, 1959*t*
        - minimally invasive approaches, 1957–1958
        - open approach, 1957
    - retrograde ureteroscopic endopyelotomy for, 1949–1950, 1951*f*–1952*f*
    - surgical approaches to, 1953–1958
    - ureterocalicostomy for, laparoscopic and robotic-assisted, 1958
    - ureteroscopy for, 191–192
- Ureteropelvic surgery, for genitourinary tuberculosis treatment, 1317–1318
- Ureteroplasty, for prune-belly syndrome, 592
- Ureteropyeloscopy, 2211, 2211*f*
- Ureterorenoscopy (URS), 2069.e2
    - morbid obesity and, 2089
    - old age and frailty and, 2089–2090
    - prior renal surgery and, 2090
    - for renal calculi
        - in calyceal diverticula, 2078
        - in horseshoe kidneys, 2079
        - in renal ectopia, 2081
        - stone composition and, 2076, 2076*f*
        - stone localization and, 2075
    - renal function and, 2088–2089
    - solitary kidney and, 2089
    - spinal deformity or limb contractures and, 2090
    - stone burden and
        - between 1 and 2 cm, 2073
        - greater than 2 cm, 2074
        - up to 1 cm, 2072
    - uncorrected coagulopathy and, 2090
    - for ureteral calculi, 2087–2088
        - duplicated collecting system and, 2087
        - in megaureter, 2087
        - outcome of, 2091–2093

        - stone burden and, 2087
        - stone composition and, 2087
        - stone localization and, 2085–2086, 2086*t*
    - urinary diversion and, 2091
    - urinary tract infection and, 2088

Ureteroscopic endoureterotomy, retrograde, for ureteral stricture disease, 1968–1969, 1969*f*

Ureteroscopic stone management, 2107–2109
- avulsion in, 2109
- perforation in, 2108
- stricture in, 2108
- submucosal stone and lost stone in, 2109

Ureteroscopic-assisted fluoroscopic access, 168–169, 168*f*

Ureteroscopy, 202*b*, 2211, 2211*f*
- antimicrobial prophylaxis for, 1199
- common supplies for, 200*t*
- dual-modality lithotripters, 244–246
- EHL with, 243.e1
- equipment for, 192, 192*f*, 193*t*, 195*f*, 196*t*, 198*f*–199*f*, 199*t*
- flexible, 244.e2
- fragmentation, 243.e2
- for genitourinary tuberculosis diagnosis, 1313–1314, 1314*f*
- indications for, 191–192
- intracorporeal lithotripters used in, 244.e4*f*
- laser fragmentation, 244.e2
- technique, 199–201, 201*f*
- ultrasonic lithotripsy, 243.e2
- ureteral injuries with, 1994–1995, 2002
    - avulsion, 2002
    - perforation, 2002

Ureterosigmoidostomy
- for classic bladder exstrophy, 564
- for continent urinary diversions, 706–707
- history of, 3233
- tumor formation and, 699

Ureterostomy
- cutaneous, for megaureter in children, 850–851, 850*f*
- for ectopic ureter, 819

Ureterotomy, intubated, for ureteropelvic junction obstruction, 1961–1962, 1963*f*

Ureteroureterostomy, 2207, 2208*f*
- laparoscopic, 817
- open, 816–817
- for ureteral anomalies, 816–817, 817*f*, 817*b*
- for ureteral injuries, upper, 1996–1997, 1997*f*
- for ureteral stricture disease, 1970–1972
  - laparoscopic or robotic approach, 1972
  - open approach, 1970–1972, 1971*f*
  - postoperative care, 1972

Ureterovaginal fistula (UVF), 266–267, 2942, 2942*b*

Ureterovascular fistulae, 2958–2959

Ureterovesical junction (UVJ), 1873, 1877, 2455–2456, 2456*f*
- with epispadias, 569
- physiology of, 1891, 1892*f*

Ureters
- bifid, 820–821
- quadruple, 821
- triplication of, 821

Urethra, 315*f*
- α-adrenergic receptors in, 2500–2501, 2501*f*
- anatomy of, 2461, 2462*f*
  - common to both genders, 2466
  - female, 2438–2439, 2439*f*, 2465–2466, 2466*f*, 2974–2975, 2974*f*, 3010
  - male, 1381–1383, 1381*f*–1384*f*, 1384*b*, 1807.e2*f*, 1807.e4*f*, 2465, 2465*f*
  - tone, 2468–2469
- caruncle of, urethral diverticula differentiated from, 2987, 2987*f*
- closure of, for classic bladder exstrophy, 545–548, 546*f*–548*f*
- distraction injuries of, 1807.e2*f*
- division of, in retropubic radical prostatectomy, 3554–3555, 3555*f*

duplication of, 310, 883–884, 884*f*

estrogens and, 2503

female, 152, 1627.e2

  in orthotopic urinary diversion, 3240–3241, 3240*f*

  radical cystectomy and, 3118

function of

  during filling/storage, 2521

  during voiding, 2521

in genitourinary tuberculosis, 1309

  treatment, 1318

hypermobility of, filling/storage failure due to, 2518

instability of, filling/storage failure due to, 2518

localization studies, 1143

male, 152

  anatomy of, 1381–1383, 1381*f*–1384*f*, 1384*b*, 1807.e2*f*, 1807.e4*f*, 2465, 2465*f*

  ultrasonography of, 85–88, 86*f*, 1384*f*

mesh perforation/extrusion at, 2883, 2883*b*, 2884*f*–2885*f*

  in midurethral sling, 2866–2868, 2867*t*, 2870*b*

mobility of, Q-tip test for, 2529

necrosis of, with transurethral vaporization of prostate, 3426

prolapse of, urethral diverticula differentiated from, 2986–2987

in prune-belly syndrome, 584, 585*f*

reconstructive surgery of, 1804–1842, 1805*b*, 1813*b*

  for amyloidosis, 1810

  anatomy of, 1807, 1807.e1*f*–1807.e7*f*

  for balanitis xerotica obliterans, 939, 940*f*

  for circumcision complications, 1811–1812

  for curvatures of penis, 1836–1838, 1838*b*

  for failed epispadias repair, 1813

  for failed hypospadias repair, 1812–1813

  for female-to-male transgender, 1841–1842, 1842*b*

  for glans dehiscence, 937, 938*f*

  for LS, 1808–1810, 1809*f*

  for meatal stenosis, 937–938, 1811

  for paraphimosis, balanitis, and phimosis, 1811

  penile transplantation, 1838–1842, 1840*f*, 1842*b*

  for PFUIs, 1828–1834, 1830*f*–1834*f*

  principles of, 1804–1807, 1806*f*–1807*f*, 1808*b*

  for reactive arthritis, 1808

  for recurrent penile curvature, 939–941, 940*f*

  for urethral diverticulum, 938–939, 939*f*, 1810–1811

        - for urethral hemangioma process, 1808
        - for urethral stricture, 938, 1814–1828, 1814*f*, 1828*b*
        - for urethrocutaneous fistula, 935–937, 936*f*–937*f*, 1810
        - for vesicourethral distraction defects, 1834*b*, 1835, 1836*b*
    - stroma of, 2468
    - support mechanisms, stress urinary incontinence and, 2596–2597, 2596*f*
    - tone of, in women, 2501
- Urethra Resistance Factor (URA), 2566
- Urethral advancement procedure, 920, 922*f*
- Urethral atresia, 620–621, 621*f*
- Urethral atrophy, with artificial urinary sphincter, 3007
- Urethral bleeding, 257–258
- Urethral calculi, 2117–2120
    - clinical presentation and evaluation of, 2117–2118
    - pathogenesis and composition of, 2117
    - primary, 2117
    - treatment of, 2118
- Urethral cancer
    - female, 1782–1785, 1785*b*
        - anatomy and pathology of, 1782–1785, 1783*f*
        - epidemiology, etiology, and clinical presentation of, 1782
        - evaluation and staging of, 1783
        - prognosis of, 1783–1784
        - recurrence after cystectomy, 1787–1789, 1789*b*
        - treatment of, 1784–1785
    - male, 1776–1782, 1782*b*
        - anterior, 1777–1781
        - carcinoma of penile urethra, 1778–1780, 1779*f*–1780*f*
        - epidemiology, etiology, and clinical presentation of, 1776–1777
        - evaluation and staging of, 1777, 1778*f*, 1778*t*
        - pathology of, 1777, 1777*f*, 1777*t*
        - posterior, 1781–1782, 1782*t*
        - recurrence after cystectomy, 1785–1787, 1786*t*, 1789*b*
        - treatment of, 1778, 1779*t*
- Urethral caruncle, 2920.e10
- Urethral catheterization

    - after laparoscopic radical prostatectomy, 3579
    - antimicrobial prophylaxis for urologic procedures and, 1193*b*, 1194*t*–1196*t*, 1197
- Urethral closure pressure profile (UCP), 2563
- Urethral compressor, 2438–2439
- Urethral dilation
    - in mesh complication, 2880
    - for neuromuscular dysfunction of lower urinary tract, 637
    - as surgical technique
        - for detrusor underactivity, 2663
        - for urethral stricture disease, 1817–1818
    - for transmen, 3071
- Urethral discharge, patient history of, 7
- Urethral diverticula (UD), 2966*f*, 2975–2992
    - anatomy and histology of, 2977, 2978*f*, 2978*t*–2980*t*
    - classification of, 2987
    - differential diagnosis of, 2983–2987
        - Gartner duct abnormalities, 2986, 2986*f*
        - periurethral bulking agents, 2987
        - Skene gland abnormalities, 2984–2986, 2986*f*
        - urethral caruncle, 2987
        - urethral mucosal prolapse, 2986–2987
        - vaginal leiomyoma, 2983–2984, 2985*f*
        - vaginal wall cysts, 2986, 2986*f*
    - etiology of, 2975–2976, 2975*f*
    - evaluation and diagnosis of, 2981–2982
        - cystourethroscopy, 2982, 2982*f*
        - history and physical examination, 2981–2982, 2981*f*
        - urine studies, 2982
        - urodynamics, 2982
    - female, 2972–2975, 2974*f*, 2987*b*
    - imaging of, 2982–2987, 2983*f*
    - management of, 2992*b*
    - pathophysiology of, 2975–2976, 2975*f*
    - presentation of, 2980–2981, 2981*b*
    - prevalence of, 2976–2977
    - reconstructive surgery for, 1810–1811

- stress urinary incontinence and, 2988–2992, 2988*f*
- surgical repair of, 2987–2988
  - alternative techniques for, 2989
  - indications for, 2987–2988
- urethral calculi within, 2977, 2977*f*
- urethral diverticulectomy for
  - complications of, 2991, 2991*f*, 2991*t*
  - excision and reconstruction, 2989, 2989*b*
  - persistence of symptoms following, 2991–2992
  - postoperative care for, 2991
  - preoperative preparation for, 2989
  - procedure for, 2989–2991, 2990*f*
  - techniques for, 2989–2992, 2989*b*

Urethral diverticulectomy, 2989*b*, 2991–2992, 2991*t*

Urethral diverticulum, 938–939, 939*f*

Urethral duplication, 621–622, 621*f*–622*f*

Urethral erosion, with artificial urinary sphincter, 3006–3007

Urethral fistula, for transmen, 3070

Urethral hair growth, for transmen, 3072

Urethral hemangioma, reconstructive surgery for, 1808

Urethral injection therapy, for female stress urinary incontinence, 2893

Urethral injury, 3057–3061
- anterior, 3060–3061, 3060.e1*f*
  - initial management of, 3060
- delayed reconstruction of, 3060–3061
  - posterior, 3059, 3059*f*
- distraction, ED with, 3059
- gunshot wounds, 3049–3050
- initial, primary realignment for, 3058–3059, 3058*f*
- and intraoperative consultation, 298–299
  - diagnosis, 299
  - incidence, 298
  - management, 299
  - mechanisms, 298–299
- with penile fracture, 3048

posterior, 3057–3060
    diagnosis of, 3057, 3057*f*
    endoscopic treatment, 3059
    etiology of, 3057, 3057.e1*f*
    immediate open, 3056
    initial management of, 3057–3059
    suprapubic cystostomy, 3057–3058
    surgical reconstruction, 3059–3060
    urethrography for, 3057, 3058*f*

Urethral instability, filling/storage failure due to, 2518

Urethral lengthening
  for bladder neck reconstruction, 688–690
  results with, 689–690
  technique for, 688–689, 689*f*

Urethral meatus, 1807.e8
  location of, 907, 907*f*–908*f*

Urethral obstruction, after pediatric renal transplantation, 1062–1063, 1062*f*–1063*f*

Urethral orifice, 1627.e2

Urethral polyp, 976, 976*f*

Urethral pressure, during bladder filling, 2515

Urethral pressure profile (UPP)
  micturitional, 2567
  in urodynamic studies, 2557

Urethral pressure profilometry
  urodynamic studies of, 2563–2564, 2564*f*

Urethral prolapse, 395, 397*f*, 975–976, 976*f*

Urethral reconstruction
  in classic bladder exstrophy, 564
  in male epispadias, 569
  for prune-belly syndrome, 592–593, 593*f*
  pubovaginal sling for, outcomes of, 2845
  for transmen, 3071–3072

Urethral region, natural defenses of, 1137

Urethral slings, stress urinary incontinence and, 2831

Urethral sphincter

- coordination of, urodynamic studies of, 2568–2569, 2569*f*–2570*f*
- CVA and, 2603
- deficiency of, intrinsic, 2518
  - quantification of, 2562
- development of, 2466
- disk disease and, 2620
- dynamics of, 682
- female, 2465–2466, 2466*f*
- male, 2465*f*
- mechanisms of, urinary incontinence and, 2596–2597, 2596*f*
- micturition and, 2494
- neurospinal dysraphism and, 2618
- obstruction of, nonrelaxing, 2521
- with Parkinson disease, 2605
- tone of, 2466

Urethral stenosis/atresia, 376

Urethral strictures, 157, 938, 1814–1828, 1814*f*, 1828*b*

- after photoselective vaporization of prostate, 3441
- after transurethral microwave therapy, 3430
- anatomic considerations for, 1814
- with bipolar transurethral resection of prostate, 3419
- decision making, 1817
- diagnosis and evaluation of, 1815–1817, 1816*f*–1817*f*
- etiology of, 1814–1815
- with holmium laser enucleation of prostate, 3438
- with monopolar transurethral resection of prostate, 3417–3418
- orthotopic urinary diversion and, 3238
- prior pelvic radiation and, 3238
- for transmen, 3070–3071, 3071*f*
- treatment, 1817–1818, 1828*b*
  - augmented anastomosis, 1821–1823, 1826*f*–1827*f*

    - dilation, 1817–1818
    - excision and reanastomosis, 1819–1820, 1819*f*–1820*f*
    - flap onlay, 1823–1827, 1824*f*–1825*f*
    - graft onlay, 1821*f*–1823*f*
    - internal urethrotomy, 1818
    - lasers, 1818–1828
    - open reconstruction, 1819–1828
    - perineal urethrostomy, 1827–1828
    - vessel-sparing technique, 1820, 1820*f*–1821*f*

- Urethral tumors, 1776–1789
  - benign, 1776
    - FEPs, 1776
    - hemangiomas, 1776
    - leiomyomas, 1776
  - malignant, Urethral cancer

- Urethral valves
  - anterior, 620
  - posterior, 602–623
    - antenatal management of, 608–610, 610*b*
    - bladder dysfunction with, 616–619
    - circumcision for, 615
    - clinical presentation of, 608–611
    - delayed presentation of, 611
    - description of, 602, 603*f*
    - diagnosis of, 607–608, 608*b*
    - epidemiology of, 602–603, 603*b*
    - initial management of, 608–611
    - laboratory studies for, 608
    - lower urinary tract and, 603–604, 605*f*–606*f*
    - nephroureterectomy, 615
    - pathophysiology of, 603–606, 604*t*, 606*b*
    - postnatal management of, 610–611, 611*b*
    - pulmonary hypoplasia with, 610–611, 610*f*
    - quality of life with, 620, 623*b*
    - radionuclide renal scan for, 608
    - renal function prognostic indicators in, 619, 620*b*
    - surgical intervention for, 611–615, 615*b*
    - transplantation in, 619–620
    - ultrasonography of, 607, 607*f*
    - upper tract diversion, 613–614, 615*f*
    - upper urinary tract and, 604–605, 606*f*
    - urinomas with, 611, 611*f*
    - valve ablation for, 611–615, 612*f*

- valve bladder syndrome with, 617–619, 617*f*–618*f*
- vesicostomy for, 612–613, 613*f*–614*f*
- vesicoureteral reflux and dysplasia, 606, 606*b*, 607*f*
- vesicoureteral reflux in, 615–616, 619*b*
- voiding cystourethrography for, 608, 609*f*

Urethrectomy
- after cutaneous diversion, 1787, 1788*f*
- after orthotopic diversion, 1787

Urethritis, 258, 436, Nongonococcal urethritis
- in differential diagnosis, 1140–1141
- as STD, 1252–1254

Urethrocutaneous fistula, 935–937, 936*f*–937*f*
- reconstructive surgery for, 1810

Urethrography, for posterior urethral injury, 3057, 3058*f*

Urethrolysis, for voiding dysfunction after pubovaginal sling, 2846, 2847*t*

Urethromeatoplasty, 918

Urethroplasty
- algorithm for, 912*f*, 914
- complications of, 934–941, 936*t*
  - balanitis xerotica obliterans, 939, 940*f*
  - glans dehiscence, 937, 938*f*
  - meatal stenosis, 937–938
  - recurrent penile curvature, 939–941, 940*f*
  - skin, 941
  - urethral diverticulum, 938–939, 939*f*
  - urethral stricture, 938
  - urethrocutaneous fistula, 935–937, 936*f*–937*f*
- genitoperineal transformation, 3066–3068
- hair-bearing skin for, 918
- outcome assessment for, 942–943
- for posterior urethral injury, 3059, 3059.e1*f*
- tubularized incised plate
  - distal, 923*f*
  - proximal, 928*f*

Urethrorrhagia, 622

Urethroscopy, for posterior urethral injury, 3057

Urethrostomy, perineal, for urethral stricture disease, 1827–1828

Urethrotomy, internal, for prune-belly syndrome, 592

Urethrovaginal fistulae, 2868, 2947–2951, 2953*b*

- diagnosis of, 2948–2950, 2949*f*–2950*f*
- etiology of, 2947–2948
- presentation of, 2947–2948, 2948*f*–2949*f*
- treatment of, 2950–2951
    - abdominal approach for, 2951
    - complications, 2951
    - follow-up, 2951
    - labial flaps, 2950–2951
    - neourethra, 2950–2951
    - operative technique for, 2951, 2952*f*
    - posterior approach for, 2951
    - vaginal approach for, 2950
    - vaginal flaps, 2950–2951

Urge suppression, behavioral training with, 2727–2729, 2728*f*

Urge-Incontinence Impact Questionnaire (U-IIQ), 111*t*

Urgency urinary incontinence (UUI)

- behavioral therapy with urge suppression for, 2727–2729, 2728*f*
- definition of, 2539, 2581, 2637, 2638*f*
- estrogens for, 2709–2710, 2711*b*
- in mesh complication, 2880
- patient history of, 4–5
- percutaneous tibial nerve stimulation for, 2750
- treatment of, 2544–2546, 2547*b*

Urge-Urinary Distress Inventory (U-UDI), 111*t*

Uric acid

- in calcium stone formation, 2023–2024
- in uric acid stone formation, 2026–2029, 2027*f*–2028*f*

Uric acid stones, 2058–2059, 2060*b*

- clinical considerations of, 2058–2059
- diagnosis of, 2060

- low urine pH, 2059, 2059*f*
- prevention of
  - conservative, 2060
  - medical treatment for, 2060
- in renal calculi, 2026–2029, 2027*f*–2028*f*
  - hyperuricosuria, 2029
  - low urinary volume, 2029
  - low urine pH, 2027–2029, 2028*f*

Uricase, 2026

Urinalysis (UA), 14, 437
- for benign prostatic hyperplasia, 3345
- color of, 14, 15*t*
- for pelvic floor disorder assessment, 2534
- physical and gross examination, 14
- for RCC, 2157
- for renal calculi, pretreatment assessment, 2070–2071
- specimen collection of, 14
- for sphincteric urinary incontinence, 2995
- turbidity, 14
- for urinary incontinence, in men, 2541
- for urinary tract obstruction, 777
- for UTI diagnosis, 1142

Urinary acidification
- in neonate, 342
- urinary tract obstruction and, 793–794

Urinary ascites, 384

Urinary bladder, surgery of, 3010

Urinary catheters, falls and, 2915

Urinary complications, 262–263

Urinary continence
- after robotic radical prostatectomy, 3581–3582, 3581*f*–3582*f*
- physiology of, 2593–2595

Urinary dipstick, sensitivity of, 16

Urinary diversion
  in antegrade nephroureteroscopic, for UTUC, 2219
  cutaneous continent, Cutaneous continent urinary diversion
  for detrusor underactivity, 2663
  for hypospadias postoperative management, 932
  minimally invasive, Minimally invasive urinary diversion
  for neuromuscular dysfunction of lower urinary tract, 636–637
  orthotopic, Orthotopic urinary diversion
  for posterior urethral valves, 613–614, 615*f*
  for urinary incontinence, in geriatric patients, 2920.e5

Urinary fistula
  with anorectal malformation, 622–623, 622*f*
  partial nephrectomy causing, 2265
  with ureterointestinal anastomoses in urinary intestinal diversion, 3186*t*, 3191–3192

Urinary flow rate, with postvoid residual, 2565

Urinary fractionated metanephrines, in evaluation of adrenal masses, 2402–2403, 2402*t*

Urinary free cortisol (UFC) evaluation, in evaluation of adrenal masses, 2400–2401

Urinary hesitancy, 4

Urinary incontinence (UI), 109–110, 399–400, 1083, 2580–2599, Pelvic floor disorders
  after retropubic radical prostatectomy, 3564
  aging and, 2582–2583
  anogenital herpes and, 2622
  associated with chronic retention, 2540
  with benign prostatic hyperplasia, 3335
  with brain tumor, 2604
  causes of, 2526
  classification of, 2580
  coital, 2540
  conservative management of, 2722–2738
    adherence to, 2734–2735

  - assessment for, 2722–2723
  - behavioral training with urge suppression, 2727–2729, 2728*f*
  - biofeedback for, 2727.e1*f*, 2729, 2729*f*, 2729.e1*f*–2729.e2*f*
  - bladder training, 2728*f*, 2730–2732, 2730.e1*t*
  - indications for, 2722
  - lifestyle modifications, 2722, 2722.e1*b*
  - patient education for, 2723
  - for pelvic floor dysfunction, 2732–2735
  - pelvic floor muscle electrical stimulation, 2729–2730
  - pelvic floor muscle training for, Pelvic floor muscle training
  - for prevention, 2735–2736
  - toileting programs for, 2730–2731, 2730.e1*t*
- continuous, 2540, 2581
- CVA and, 2602
- daytime, Bladder and bowel dysfunction
- definition of, 2539, 2580
- diagnosis of, 2526
- diet and, 2586
- epidemiology of, 2581–2582
- female
  - retropubic suspension surgery for, Retropubic suspension surgery
  - urethra and, 2466
  - use of injectable agents for, 2890–2891, 2891*t*
- female sexual dysfunction and, 1655–1656
- general comments on, 2581–2582
- in geriatric patients, 2917–2920
  - absorbent products for, 2920.e6
  - behavioral therapies for, 2920.e3
  - clinical evaluation of, 2920
  - costs of, 2918
  - established, 2919
  - history for, 2920.e1
  - laboratory testing for, 2920.e2
  - negative impacts of, 2918–2919
  - pharmacotherapies for, 2920.e3–2920.e4
  - physical examination for, 2920.e1
  - PVR assessment, 2920.e1
  - risk factors of, 2918
  - surgical therapies for, 2920.e4–2920.e6
  - transient, 2919
  - treatment of, 2920
  - urine containment for, 2920.e6

  - urodynamic studies for, 2920.e2
  - voiding diaries, 2920.e1–2920.e2
- giggle, 2540

- hemodynamic changes with, 791–792, 793*b*
  - bilateral ureteral obstruction, 791–792, 792*f*
  - glomerular filtration and, 791
  - partial ureteral obstruction, 792
  - renal blood flow, 791–792
  - renal vascular resistance, 791–792
  - unilateral ureteral obstruction, 791, 791*f*

hydrogen ion transport and, 793–794
hypertension with, 794
laboratory studies for, 777–778
  biomarkers of, 778
  fractional excretion of sodium, 777
  renal function assessment, 777–778
  urinalysis, 777
pathological changes of, 781–786
pathophysiology of, 776–797
postobstructive diuresis after, 796
prevalence of, 776
progressive renal dysfunction and, 776, 777*f*
renal recovery after, 795–796
sodium transport and, 793
treatment of, 795–796, 797*b*
  pain management, 795
  renal drainage, 795
  surgical intervention for, 796
tubular function effects of, 792–794
tubulointerstitial fibrosis with, 786–790, 790*b*
urinary acidification and, 793–794
urinary concentration ability with, 793
urine egress from kidney in, 794
Whitaker test for, 780

Urinary tract reconstruction
for cloacal exstrophy, 578–579
  modern staged, 578, 578*t*
  osteotomy role in, 578–579, 579*f*
  single-stage, 579
in pediatric patients
  antireflux, 683–685, 685*b*
  augmentation cystoplasty for, 691–706, 702*b*, Augmentation cystoplasty
  bladder neck reconstruction, 685–690, 690*b*
  continent urinary diversions, 706–713, 711*b*, Continent urinary diversions
  patient evaluation for, 681–682, 683*b*
  patient preparation for, 682–683, 683*b*
  summary for, 713
  urodynamics for, 681–682

Urinary tract trauma, upper, 1982–2004

Urinary urgency

- with holmium laser enucleation of prostate, 3438
- patient history of, 3–4

Urine

- abnormalities, in BPS/IC etiology, 1232.e9–1232.e10
- acidification of, urinary tract obstruction and, 793–794
- analysis, Urinalysis
- chemical examination of, 15–27, 25*b*–27*b*
    - additional serum studies, 26
    - bacteria, 23, 24*f*
    - Berger disease, 17
    - bilirubin and urobilinogen, 20
    - blood/hematuria, 16
    - casts, 23, 23*f*–24*f*
    - cells, 21–23, 21*f*–23*f*
    - crystals, 23, 24*f*
    - CT and MRI, 27
    - cystometrography and multichannel urodynamic studies, 26–27
    - cystourethroscopy, 26
    - expressed prostatic secretions, 24, 25*f*
    - glomerular hematuria, 16–17, 16*t*, 17*f*
    - glucose and ketones, 19–20
    - intravenous pyelogram, and plain radiographs, 27
    - leukocyte esterase and nitrite tests, 20–21, 20*f*
    - microscopy technique, 21
    - nonglomerular hematuria, 17–18
    - office diagnostic procedures, 26
    - parasites, 24, 25*f*
    - pH, 15–16
    - prostate-specific antigen, 25
    - proteinuria, 15*t*, 18–19
    - radiologic imaging, 27
    - serum laboratory studies, 25
    - specific gravity and osmolality, 15
    - ultrasonography, 27
    - urinary markers, 25–26
    - urinary sediment, 21
    - uroflowmetry and ultrasound, for postvoid residual, 26
    - yeast, 22*f*, 23
- concentration of, with urinary tract obstruction, 793

crystallization in, 2009
culture, for UTI diagnosis, 1142–1143, 1143*f*
egress from kidney, in urinary tract obstruction, 794
natural defenses of, 1137
pH, low
    in calcium stone formation, 2024–2025
    in uric acid stone formation, 2027–2029, 2028*f*
physical and gross examination of, 14
volume of, low, in uric acid stone formation, 2029

Urine containment, for urinary incontinence, in geriatric patients, 2920.e6

Urine culture, 437–438
reconstruction and, 682

Urine cytology
of bladder tumor, 3079, 3079*f*, 3080*t*
endoscopic evaluation and collection of, 2211
for non-muscle-invasive bladder cancer surveillance, 3109
for UTUC diagnosis, 2192

Urine dipstick tests, 437

Urine flow rate, male urinary incontinence and, 2543

Urine leaks
after partial nephrectomy, 263–264
after upper tract urologic surgery, 263–264
indications for intervention for, 1071
with intestinal anastomoses, 3180*t*
management, 263–264, 264*f*–265*f*
persistent, 1070
renal exploration with repair of, 1072
risk factors and diagnosis, 263, 264*f*

Urine microscopic examination, 437

Urine transport, 1891–1894
bladder filling and neurogenic vesical dysfunction effects on, 1893
diuresis effects, 1893
ureteropelvic junction, physiology of, 1891, 1892*f*

- ureterovesical junction, physiology of, 1893–1894
- urinary bolus propulsion in, 1892–1893, 1893*f*

Urine-based biomarkers, 3485–3487

Urinoma
- hematoma compared with, 1988
- for pediatric genitourinary trauma, 1071, 1071*f*
- with posterior urethral valves, 611, 611*f*

Urobilinogen, in urine, 20

Urocutaneous fistulae, 2962

Urodynamic catheters, 155

Urodynamic observations, of urinary incontinence, 2580

Urodynamic stress incontinence (USI), 2543

Urodynamic stress test, 2562

Urodynamic studies (UDS), 2550–2579
- of acute urinary retention, 3338, 3338*f*
- after radical pelvic surgery, 2620–2621
- ambulatory, 2571–2574
  - clinical utility of, 2571–2574
- analysis and interpretation in, 2559–2569, 2569*b*
- antimicrobial prophylaxis for, 1197
- for benign prostatic hyperplasia, 3347
- of bladder diverticula, 2967
- clinical applications of, evidence-based, 2574–2578
  - guidelines, 2574
  - in lower urinary tract symptoms, 2576–2577
  - in neurogenic lower urinary tract dysfunction, 2577–2578
  - in stress incontinence in women, 2574–2576
- in clinical practice, 2550–2551, 2551*b*
- components of, 2556–2557, 2557*f*
- conduction of, 2551–2554
- cystometrogram in, 2556, 2557*f*
- definition of, 2550
- of detrusor underactivity, 2650, 2651*f*

electromyography in, 2557, 2559

equipment for, 2557–2559, 2559*b*

eyeball, 2534

of filling and storage phase, 2552*t*–2553*t*, 2559

- detrusor overactivity and impaired compliance, 2560–2561, 2560*f*–2561*f*
- leak point pressures, 2561–2563, 2562*f*–2563*f*
- normal, 2559–2560, 2559*f*
- occult stress incontinence, 2563
- stress-induced detrusor overactivity, 2563, 2563*f*
- urethral pressure profilometry, 2563–2564, 2564*f*

guidelines for, 2550

key points of, 2578*b*

for male urinary incontinence, 2543–2544

of MS, 2607

multichannel, 2536, 2565*f*

neurologic injury and, 2612–2614

in overactive bladder, 2645

Parkinson disease and, 2605

for pelvic floor disorders assessment, 2534–2536, 2536*b*

postvoid residual in, 2556

preparation for, 2551–2554, 2554*b*–2556*b*

pressure-flow studies in, 2557

room for, 2552–2553

rules for, 2551

signal transmission and transducers for, 2558

of sphincteric urinary incontinence, 2997

terminology for, 2554*b*–2556*b*

of urethral diverticula, 2982

urethral pressure profile in, 2557

of urinary incontinence, in geriatric patients, 2920.e2

for urinary tract reconstruction, in pediatric patients, 681–682

uroflowmetry in, 2556, 2557*f*, 2558–2559

video, Videourodynamics

of voiding and emptying phase, 2564–2566

- bladder outlet obstruction in men, 2566–2567, 2567*f*
- bladder outlet obstruction in women, 2567–2568
- normal, 2564–2565, 2564*f*–2565*f*

    - sphincter coordination, 2568–2569, 2569*f*–2570*f*
    - voiding pressure-flow studies, 2565–2566, 2566*f*
  - of voiding dysfunction, functional classification and, 2551

Urodynamic systems, 2557–2558

Urodynamic testing
  - setup, 480–486, 480*f*
  - in urine, 26

Uroenteric fistulae, 2952–2953
  - pyeloenteric, 2953–2955, 2953*f*
  - urethrovaginal, Urethrovaginal fistulae
  - vesicoenteric, 2953*t*, Vesicoenteric fistulae

Uroflow, 942

Uroflowmetry
  - for benign prostatic hyperplasia, 3346–3347, 3346*f*
  - test equipment, 480–481, 480*f*–481*f*
  - in urodynamic studies, 2556, 2557*f*, 2558–2559

Urogenital Distress Inventory, 110, 111*t*

Urogenital hiatus, 2434

Urogenital imaging, pediatric, 403–425
  - computed tomography for, 416–418
  - conventional radiography, 415
  - DMSA renal cortical scintigraphy, 418
  - magnetic resonance imaging for, 412–415
  - technique of, 403
    - ionizing, 403, 403*b*
    - nonionizing, 403, 403*b*
  - ultrasonography for, 404–412

Urogenital sinus, 380–382
  - abnormalities of, 1019*b*
    - classification of, 1019–1025, 1020*f*–1021*f*
    - evaluation of, 1019–1021, 1022*b*
    - history and physical examination for, 1021–1022
    - outcomes of reconstruction, 1037*b*
    - radiographic and endoscopic evaluation of, 1023–1025, 1023*f*–1024*f*

    - urogenital mobilization, 1036*b*
  - formation of, 320*t*, 328, 330*f*–331*f*
  - surgical reconstruction of, Reconstructive surgery, for disorders of sex development and urogenital sinus

- Urogenital triangle
  - female, 2434
  - male, 2450, 2451*f*
- Urogynecologic fistulae, 2946
  - ureterovaginal, 2942, 2942*b*
  - urethrovaginal, 2947–2951
  - vesicouterine, 2946–2947, 2947*b*
  - vesicovaginal, 2924–2926
- Urolithiasis
  - CT and, 48, 49*f*
  - lithotripsy for, Lithotripsy
  - medical management, 350–351, 351*b*
  - in pregnancy, 286–288, 288*b*
    - etiology, 286
    - evaluation, 286–288
  - ureteroscopy for, 191
- Urologic cancer, in geriatric patients, 2920.e13
- Urologic considerations, in pregnancy, 282–295
- Urologic disorders, and metabolic syndrome, 1420–1422
  - bladder cancer, 1421
  - low testosterone and erectile dysfunction, 1422
  - lower urinary tract symptoms, 1421
  - overactive bladder, 1421
  - prostate cancer, 1421–1422
  - renal insufficiency, 1420
  - renal stones, 1420–1421
  - tumor, 1421
- Urologic evaluation of child, 388–402
- Urologic malignancy, during pregnancy, 292–293

- angiomyolipoma, 293
- bladder tumors, 293
- renal tumors, 292–293

Urologic oncology, nuclear medicine in, 42–44

Urologic patient, evaluation of, 1–27, 13*b*, 27*b*

Urologic surgeon, 145

Urologic surgery
- adverse events during, 145
- blood products for, 147–148
  - biologically active agents, 148
  - component therapy, 147
  - dry matrix agents, 147
  - hemostatic agents, 147
  - massive transfusion protocol, 147
  - packed red blood cells, 147
- complications of, 260–281, 281*b*
  - bowel injury, 275–281, 276*f*
  - classification of, 260–261
  - Clavien-Dindo scale, 260–261, 261*t*
  - lower tract urinary, 267–269
  - neuromuscular, 261–262
  - physiologic, 261
  - positional, 261–262
  - ureteral injury, 264–267
  - urinary, 262–263
  - urine leaks, after upper tract urologic surgery, 263–264
  - vascular, 269–275, 270*f*
- drains during, 148
  - Blake, 148
  - Jackson-Pratt, 148
  - Penrose, 148
  - pigtail, 148
- hypothermia during, 145
- incision closure for, 148–151
  - fascial closure techniques, 150–151
  - retention sutures, 151
  - skin closure, 150–151
- lithotomy position during, 146
- patient environment during, 145–147

        - open abdominal sacrohysteropexy, 2822–2823, 2824*t*
        - sacrospinous, 2817–2820
        - transvaginal uterosacral ligament, 2817, 2819*t*
    - uterine sparing and, 2815–2823, 2816*t*
- Uterine RMS, in pediatric patients, 1120

Uterine tube, 324–325, 324*f*–325*f*

Uterosacral fold, 2427–2428, 2429*f*

Uterosacral hysteropexy, minimally invasive, 2820–2822, 2821*t*

Uterosacral ligament, 2429–2430, 2431*f*

- surgical anatomy of, 2789*f*, 2790, 2791*f*

Uterosacral ligament suspension, for apical vaginal vault prolapse repair, 2790–2793

- abdominal approach to, 2791, 2793*f*
- high suspension, 2790–2791, 2792*f*
- results of, 2792–2793, 2794*t*

Uterovaginal canal, 324*f*

Uterus

- anatomy of, 2436
- imaging of, 2440–2441, 2441*f*–2442*f*
- round ligament of, 321

Uterus corpus, 325, 325*f*

Uterus didelphys, 327

UTIs, Urinary tract infections

Utricle, 315*f*

UTUC, Upper tract urothelial cancer

UUI, Urgency urinary incontinence

UVF, Ureterovaginal fistula

UVJ, Ureterovesical junction

V

Vaccination, for GU cancers, 1339–1340, 1340*f*

- genitourinary tumors, 1341–1342, 1342*f*
- kidney cancer, 1340–1341
- prostate cancer, 1341

Vacuum therapy, and PD, 1615, 1617*t*

Vagina, 325–327, 326*f*–327*f*

- anatomy of, 2438
- disorders of, 978–986, 982*b*
  - associated findings, 981–982
  - hymenal skin tags, 978–979, 979*f*
  - imperforate hymen, 978–979, 979*f*
  - transverse vaginal septum, 979–980, 979*f*–980*f*
  - vaginal agenesis, 980–981, 981*f*
  - vaginal atresia, 980
  - vertical fusion, 979–981
- embryology of, 973–974, 974*f*, 974*b*
- leiomyoma of, urethral diverticula differentiated from, 2983–2984, 2985*f*

Vaginal agenesis, 327, 980–981, 981*f*

Vaginal atresia, 980

Vaginal birth, urinary incontinence and, 2583

Vaginal cells, receptivity of, in UTIs, 1135–1136, 1135*f*

Vaginal cones

- for pelvic floor muscle training, 2722.e2*b*–2722.e4*b*, 2726, 2726.e1*f*
- for urinary incontinence, in geriatric patient, 2920.e3

Vaginal delivery, for congenital urologic conditions, 290

Vaginal discharge, 397

Vaginal hysterectomy, for uterine prolapse, 2814

Vaginal mesh

- exposure
  - after mid-urethral sling surgery, 2864, 2864*f*
  - complications from, 2880, 2881*f*
- removal, complications from, 2882, 2882*b*

Vaginal pain, in mesh complication, 2881

Vaginal paravaginal repair, for pelvic organ prolapse, 2780*t*, 2783, 2784*f*–2785*f*

Vaginal prolapse, after retropubic suspension surgery, 2770–2771

Vaginal pull-down maneuver, 974, 975*f*

Vaginal reflux, pediatric, 660

Vaginal replacement surgery, 982–984, 985*b*

  intestinal neovagina creation for, 983–984, 983*f*–984*f*

  skin neovagina creation for, 982–983, 982*f*

Vaginal rhabdomyosarcoma, 397

Vaginal RMS, in pediatric patients, 1119–1120, 1119*f*

Vaginal wall cysts, urethral diverticula differentiated from, 2986, 2986*f*

Vaginectomy, 3064–3066, 3064*f*–3068*f*

Vaginismus, female sexual dysfunction and, 1637

Vaginitis, 1140, 1271–1272, 1272*t*

Vagino-obturator shelf (VOS) repair, 2767–2768

  results with, 2768

  suspensions in, configuration of, 2758

  technique for, 2767–2768, 2767*f*

  tissue approximation in, 2759

  urethral elevation in, 2758

Vaginoplasty, 3062

  initial management, timing, and principles for, 1026, 1026*f*, 1028*f*–1029*f*

Valid surrogate end point, 104

Validated questionnaires, 476–477

Validity, definition of, 109

Valrubicin, for non-muscle-invasive bladder cancer, 3104

Valsalva leak point pressure (VLPP), 2562, 2597

Valsalva maneuver, 2902

Valve bladder syndrome, 617–619, 617*f*–618*f*

Vancomycin

  prophylaxis with, for uncomplicated urologic procedures, 1194*t*–1196*t*

  for UTIs, 1150*t*–1151*t*

Vanilloids, to facilitate bladder filling and urine storage, 2709

Vanillylmandelic acid testing, for pheochromocytoma, 2377

Vanishing testis, 959–960, 960*f*

Vardenafil (Levitra)
- to facilitate bladder filling and urine storage, 2682*t*, 2701
- for ureteral relaxation, 1899

Varicocele, 899–903, 900*b*, 1440, 1450
- associated pathologic processes, 900–901
- diagnosis and classification of, 900, 900*t*
- epidemiology of, 899–900
- hormonal function, 901
- intratesticular, 901–902
- pathogenesis of, 899–900
- sclerotherapy or embolotherapy for, 903, 903.e1*f*
- semen quality in, 901
- surgical repair of, 902, 902*t*
- testicular histology, 901
- treatment for, 902–903
- varicocelectomy for
  - retroperitoneal or laparoscopic, 902–903, 903*f*
  - subinguinal or inguinal microsurgical, 902

Varicocelectomy, 1855
- complications of, 1482
  - hydrocele, 1482
  - testicular artery injury, 1482
  - varicocele recurrence, 1482
- laparoscopic, 902–903, 903*f*, 1477
- microsurgical inguinal and subinguinal operations for, 1477–1481
  - anesthesia for, 1477
  - approaches for, 1478, 1478*f*–1479*f*, 1478*t*
  - delivery of testis, 1478*t*, 1480–1481, 1481*f*
  - dissection of cord, 1479–1480, 1479*f*–1481*f*
- radiographic occlusion technique for, 1481–1482
- results for, 1482–1483
- retroperitoneal, 902–903, 903*f*, 1476–1477, 1476*f*
- scrotal operations for, 1476
- subinguinal or inguinal microsurgical, 902

Vas deferens, 1850–1853
  anatomy of, 1377*b*
    arterial supply, 1377
    gross structure, 1376, 1376*f*–1377*f*
    lymphatic drainage, 1377
    microanatomic architecture, 1376–1377
    nerve supply, 1377
    venous drainage, 1377
  anomalies of, 903
  blood supply of, 1454, 1454*t*
  dissection of, in laparoscopic radical prostatectomy, 3573–3574, 3574*f*
  in genitourinary tuberculosis, 1309
  imaging of
    transrectal ultrasound, 1444.e3
    vasogram, 1377
Vas isolation, methods of, 1850
Vascular anomaly, 338–339
Vascular changes, with aging, 2906
Vascular complications, after RPLND, 2244
Vascular complications, of urologic surgery, 269–275
  access technique, comparison of, 271–272
  diagnosis of, 274–275, 275*f*
  epigastric vessels, injury of, 272
  injury, mechanisms of, 271
  major vessels, injury of, 272–273, 273*f*
  management, 270, 270*f*
    intraoperative vascular complications, 269–270
  postoperative vascular complications, 274
  stapler malfunction, 273–274, 274*f*
  vascular incidents, management of, 272, 272*f*
  vascular injury, during abdominal access, 271
Vascular endothelial growth factor (VEGF)
  inhibitors of
    for metastatic bladder cancer, 3130–3131
    for metastatic RCC, 2326–2327, 2333–2337, 2333*t*–2335*t*, 2336*f*, 2337*t*

  - in RCC, 2146

Vascular evaluation, in ED, 1521–1523

Vascular injury
  - during abdominal access, 271
  - during laparoscopic and robotic surgery, 229–230
  - laparoscopic kidney surgery causing, 2306–2307
  - during radical nephrectomy, 2261

Vascular invasion, 3512

Vascular malformations, 888, 888*f*

Vascular reconstruction, RPLND with, 1718–1719, 1719*f*

Vascular surgery, ureteral injuries with, 1993

Vascular transposition, for laparoscopic pyeloplasty, 1956

Vascular-targeted photodynamic (VTP) therapy, 3632, 3637*t*

Vasculature
  - adrenal, 2345, 2348*f*–2349*f*, 2355*f*, 2356, 2405–2406, 2406*f*
  - of bladder, 2455, 2456*f*, 2462–2463, 2464*f*
  - of epididymis, 1375
  - of pelvis
    - female, 2432–2433, 2433*f*
    - male, 2451–2452, 2451*t*
  - of penis, 1807.e4*f*
  - of prostate, 1380, 1380*f*
  - renal, 1869–1870
  - of scrotum, 1843
  - of testis, 1370–1371, 1372*f*
  - of urethra, 2438–2439, 2439*f*
  - of uterus, 2436
  - of vagina, 2438

Vasectomy, 1440, 1850–1853, 1853*b*
  - conventional technique for, 1850–1851
  - failure, complication of scrotal surgery, 1856
  - minimally invasive, 1851, 1851*f*

  - no-scalpel technique for, 1851–1853, 1852*f*
  - prostate cancer and, 3464
  - reversal, 1853

Vasoactive drugs, for PE, 1572.e2

Vasoactive intestinal polypeptide, 1535

Vasoconstriction, renal hormone effects, 1913

Vasodilation, renal hormone effects, 1913

Vasoepididymostomy, 1467–1471
  - indications for, 1468
  - intussusception, 1469–1470, 1470*f*
  - long-term follow-up evaluation and results, 1471
  - techniques for, and microsurgical end-to-side, 1468–1469, 1468*f*–1469*f*, 1468*t*
  - varicocelectomy and, 1470

Vasoepididymostomy, for chronic scrotal pain syndrome, 1221

Vasogram, of vas deferens, 1377

Vasography, 1457–1460
  - complications of, 1458–1459
    - hematoma, 1459
    - injury to vasal blood supply, 1459
    - sperm granuloma, 1459
    - stricture, 1458–1459
  - fine-needle, 1459–1460
  - in male, 1444
  - techniques, and interpretation of findings, 1457–1458, 1457*f*–1459*f*
  - transrectal and seminal vesiculography, 1459–1460

Vasopressin, renal vascular tone control by, 1913

Vasovasostomy, 1460–1467
  - and anastomosis in convoluted, 1465–1466, 1466*f*
  - anastomotic techniques for, 1463–1464
  - anesthesia for, 1460
  - for chronic scrotal pain syndrome, 1221
  - crossed, 1466
    - technique for, 1466, 1466*f*

    - long-term follow-up evaluation for, 1467
    - and microsurgical multilayer microdot method, 1464–1465, 1464*f*–1465*f*
    - and multiple vasal obstructions, 1462
    - postoperative complications of, 1467
    - postoperative management for, 1467
    - preoperative evaluation for, 1460
        - laboratory tests, 1460
        - physical examination, 1460
    - preparation of vasa, 1461, 1461*f*–1462*f*
    - set-up for, 1464
    - surgical approaches for
        - inguinal, 1460–1461
        - scrotal, 1460, 1461*f*
    - and transposition of testis, 1466, 1467*f*
    - and varicocelectomy, 1462–1463
    - and vasoepididymostomy, 1461–1462, 1463*t*
    - wound closure, 1466–1467
- VCUG, Voiding cystourethrogram
- VDR, Vitamin D receptor
- VEGF, Vascular endothelial growth factor
- Vein grafts, for urethral and penile reconstruction, 1806
- Velocity of sound, 70*f*
- Vena caval replacement, 2276–2277, 2277*f*
- Vena caval resection, in retroperitoneal tumors, 2243
- Vena caval thrombectomy, 2266–2278, 2278*b*
    - bypass techniques for, 2275–2276, 2275*f*–2276*f*, 2275.e1*f*, 2276.e1*f*
    - IVC filtration and permanent interruption for bland thrombus, 2277
    - level I, right-sided tumor technique, 2267–2269, 2267.e1*f*, 2269.e1*f*, 2270*f*
    - level II, left-sided tumor technique, 2269–2270, 2269.e1*f*, 2271*f*
    - level III-IV
        - combined intra-abdominal and intrathoracic approach, 2274–2275, 2274*f*, 2274.e1*f*
        - intra-abdominal approach technique, 2270–2274, 2271*f*–2274*f*, 2273.e1*f*
    - patching, replacing, and interrupting of IVC in, 2276–2277, 2277*f*
    - perioperative complications, 2277–2278

    preoperative considerations for, 2266–2267, 2267*t*, 2268*f*–2269*f*

Veneficus, 427–428

Venereal warts, Condylomata acuminata

Venography, 1444, 1444.e1

Venous drainage, 1807.e8–1807.e9

Venous flow, pneumoperitoneum effects on, 220–221

Venous gas embolism, 181

Venous reconstruction, in ED, 1537

Venous supply, to male pelvis, 2452

Venous system

    of retroperitoneum, 1672–1674, 1672.e1*f*

    surgical anatomy of, 3548, 3549*f*

Venous thromboembolism (VTE), 278–280, 279*t*–280*t*

    after RPLND, 1731

    prophylaxis for, in urologic surgery, 128–130, 129*t*–131*t*, 131*b*

Venous tumor thrombus

    laparoscopic radical nephrectomy for, 2298

    in RCC, 2160

    surgery for, Vena caval thrombectomy

Venovenous bypass (VVB), for vena caval thrombectomy, 2275, 2275*f*, 2275.e1*f*

Ventral corporal lengthening procedures, 913, 915*f*–916*f*

Ventral penile curvature, 911–914, 916*b*

    artificial erection for, 911–912

    assessment and management of, 911–914

    dorsal shortening technique for, 912–913, 915*f*

    goniometer for, 912

    significance of, 911

    ventral corporal lengthening procedures for, 913, 915*f*–916*f*

Ventriculoperitoneal (VP) shunts, 461

Verapamil, for PD, 1612, 1617*t*

Veress needle, 463, 464*f*
  for achieving transperitoneal access and establishing pneumoperitoneum, 207–209
  complications related to, 224
  vascular injury, 469*f*
Verrucous carcinoma (Buschke-Lowenstein tumor)
  as neoplastic condition, 1296–1297, 1299*f*
  of penis, 1742.e1
Vertebral column abnormalities, with cloacal exstrophy, 575
Vertical fusion, abnormalities of, 979–981
Verumontanum, 315*f*, 1382, 1382*f*–1383*f*
Vesicle pain, patient history of, 2
Vesicoamniotic shunt placement *versus* fetal cystoscopy, 365–366, 367*f*
Vesicobullous disorders, 1283–1286, 1284*b*
  bullous pemphigoid, 1284–1285, 1285*f*
  dermatitis herpetiformis, 1285
  Hailey-Hailey disease, 1285–1286, 1286*f*
  linear IgA bullous dermatosis, 1285, 1285*f*
  pemphigus vulgaris, 1284, 1284*f*
Vesicoenteric fistulae, 2953*t*, 2955*b*
  etiology of, 2952–2953, 2953*t*
  presentation of, 2952–2953, 2953*t*
Vesicopelvic ligament, 2429–2430
Vesicostomy
  continent, 710–711
  cutaneous, 690–691
    for posterior urethral valves, 612–613, 613*f*–614*f*
    for prune-belly syndrome, 592, 592*f*
Vesicoureteral reflux (VUR), 330, 374, 374*f*–375*f*, 399, 489–517, 836–846, 836*b*, 1139, 1938
  after pediatric renal transplantation, 1062, 1062*f*
  assessment of, 95
  associated anomalies and conditions, 507–511

  - bladder diverticula, 509–510, 509.e1*f*
  - megacystis-megaureter association, 510
  - other anomalies, 510
  - pregnancy and reflux, 510–511, 511*b*
  - renal anomalies, 510
  - ureteral duplication, 508–509, 508.e1*f*
  - ureteropelvic junction obstruction, 507–508, 509*f*
- causes of, 495–497
  - clinical correlates, 496–497, 497*f*
  - primary reflux, 495
  - secondary reflux, 495–496, 496*f*
- clinical presentation of, 836
- Cohen Cross-Trigonal technique for, 840, 841*f*
- complications of ureteral reimplantation for, 844–846
  - contralateral reflux, 844
  - obstruction, 844–846
  - persistent reflux, 844
- controversies in usage of invasive investigations, 507
  - American Academy of Pediatrics Guidelines for febrile urinary tract infection diagnosis and management in young children, 507, 508*t*
  - National Institutes for Clinical Excellence Guidelines, 507
- cortical defects, 498–501, 500*b*
  - acquired renal scars, 499–500
  - congenital defects *versus* acquired scar, 498–499
  - pathophysiology of acquired scarring, 500–501, 500*f*–501*f*
  - reflux-associated renal dysplasia, 499, 499*f*, 499*t*, 499.e1*f*
- defecation disorders and, 667, 667.e1*f*
- definition of, 836
- demographics, 489–490, 490*b*
  - age, 490, 490*t*
  - prevalence, 489
  - race, 490
  - reflux in the fetus, 490
  - sex, 489–490
- diagnosis and evaluation of, 501–503, 502*b*, 1938
  - confirmation of urinary tract infection, 501–502
  - evaluating urinary tract infection, 502–503, 503*f*
- early complications of, 844–846
- embryology of ureterovesical junction, 493
- endoscopic treatment of, 846–849
  - follow-up for, 847–848
  - injection technique, 846–847, 847*f*

  - materials used for, 848
  - recurrence after, 848–849
- with epispadias, 569
- extravesical procedures for, 840–842, 842*f*–843*f*
- functional anatomy of the antireflux mechanism, 493–495, 494*f*, 494*t*, 495*b*
- Glenn-Anderson technique for, 840, 840*f*
- grading of, 497–498, 498*f*, 498*t*
- historical perspective, 489
- incision for, 836, 837*f*–839*f*
- inheritance and genetics, 490–492, 492*b*
  - genes involved, 491–492, 492*f*–493*f*
  - sibling reflux, 490–491
- intravesical procedures for, 836–840
  - ureter mobilization, 836–840, 837*f*–839*f*
- long-term complications of, 846
  - obstruction, 846
  - recurrent or persistent reflux, 846
- lower urinary tract, assessment of, 503–505
  - cystographic imaging, 503–504, 504*f*
  - cystoscopy and the positioning of the instillation of contrast cystogram, 504–505
- minimally invasive procedures for, 842–844
- natural history and management, 511–517, 516*b*
  - antibiotic controversies and potential new approaches, 514–515
  - individualizing patient care, 516–517, 517*f*
  - landmark studies, 515–516
  - medical management: continuous antibiotic prophylaxis, 513–514, 513*t*

  - resolution by age, 512, 512*f*
  - resolution by grade, 511
  - spontaneous resolution, 511
- neural tube defects and, early intervention for, 628
- in neuromuscular dysfunction of lower urinary tract, 638–639, 638*f*, 639*b*
- in pediatric patients, 653–654
- Politano-Leadbetter technique for, 837*f*–839*f*, 840
- with posterior urethral valves, 615–616, 619*b*
- postoperative evaluation of, 844
- recommendations for, 374
- reoperative reimplantation for, 846
- robotic-assisted laparoscopic ureteral reimplantation- extravesical for, 844, 845*f*

- surgical management of, 836
- treatment of, 1938
- upper urinary tract, assessment of, 505–507
  - controversies in usage of invasive investigations, 506
  - rationale for serial assessment of upper tracts, 505
  - renal scintigraphy, 505–506, 506*f*
  - renal scintigraphy and the top-down approach, 506–507
  - renal sonography, 505
- ureteral function relation with, 1898–1899, 1899*f*
- ureteropelvic junction obstruction with, 1943
- urinary tract dysfunction with, 2615
- urinary tract infection and, 497, 497*b*
- Valsalva maneuver and, 2902

Vesicoureteral reflux and dysplasia (VURD), posterior urethral valves and, 606, 606*b*, 607*f*

Vesicourethral distraction defects, 1834*b*, 1835, 1836*b*

Vesicouterine fistulae, 2946–2947, 2947*b*

- diagnosis of, 2946–2947, 2946*f*–2947*f*
- etiology of, 2946
- management of, 2946–2947
- presentation of, 2946

Vesicouterine pouch, 2427–2428, 2429*f*

- bladder, 3010

Vesicovaginal fistula (VVF), 2924–2926, 2925*f*, 2925*b*, 2942*b*

- abdominal techniques for, 2937
  - suprapubic intraperitoneal or extraperitoneal, 2937, 2937*f*–2938*f*
  - transvesical, 2937
  - vaginal *versus*, 2933–2934, 2933*t*
- adjuvant procedures in repair of, 2939–2942
  - greater omentum, 2940
  - Martius flap, 2939–2940, 2939*f*
  - other flap and graft techniques, 2940, 2941*f*
  - peritoneal flap, 2940, 2940*f*
- causes of, 2927*b*
- conservative and minimally invasive therapy for, 2931–2932, 2932*f*
- etiology of, 2925, 2925*f*, 2925*b*

- history of, 2929
- intraoperative risk factors for, 2927–2930
  - cystoscopy for, 2929, 2929*f*
  - diagnosis of, 2928
  - evaluation of, 2928
  - imaging for, 2929, 2930*f*–2931*f*
  - physical examination of, 2928–2929, 2928*f*
  - presentation of, 2928
  - urine studies for, 2929–2930
- laparoscopic approaches to, 2937–2939, 2939*t*
  - transabdominal transvesical, 2940
- posthysterectomy, 2926–2927
- prevalence of, 2925
- robotic approaches to, 2937–2939
- surgery for
  - abdominal *versus* vaginal approach, 2932–2933, 2933–2934, 2933*t*
  - adjuvant flaps or grafts, 2934
  - antibiotics, 2934
  - estrogen supplementation, 2934
  - excision *versus* no excision, 2934
  - immediate *versus* delayed, 2933
  - indications for, 2934–2935
  - outcomes of, 2942
  - postoperative drainage, 2934
  - preoperative counseling for, 2934–2935
- treatment for, 2931–2942
- urinary diversion and, 2940–2942
- vaginal techniques for, 2935–2937
  - abdominal *versus*, 2933–2934, 2933*t*
  - complications with, 2936–2937
  - other transvaginal techniques, 2937
  - vaginal flap or flap-splitting technique, 2935–2936, 2935*f*–2936*f*

Vesicovaginal space, 2427, 2429*f*

Vesiculodeferential artery, 1377

Vessel-sparing technique, for urethral stricture disease, 1820, 1820*f*–1821*f*

Vestibular cysts, 976–977, 977*f*

Vestibule, 1627.e1
- disorders of, 975–977, 977*b*
  - ectopic ureteral insertion, 977, 978*f*

- prolapsed ureterocele, 977, 978*f*
- urethral polyp, 976, 976*f*
- urethral prolapse, 975–976, 976*f*
- vestibular cysts, 976–977, 977*f*

Veterans Affairs Cooperative Study, 3385

VHL, von Hippel-Lindau disease

VHL gene, 2141–2143, 2143*t*, 2144*f*, 2332–2333, 2333*f*

Viagra, Sildenafil

Vicryl suture, 149–150

Video-endoscopic systems, 185, 186*f*–187*f*

Videourodynamics (VUDS), 1048, 1048*f*, 2569–2571, 2571*b*, 2572*f*

- for benign prostatic hyperplasia, 3347
- for bladder neck dysfunction, 2570, 2570*f*
- for BOO diagnosis in women, 2570, 2570*f*
- for LUTS in men, 2570, 2571*f*
- methods of, 2570
- for neuropathic voiding dysfunction, 2573*f*
- for pelvic floor disorders, 2535
- for voiding phase dysfunction, 2570

Vinblastine-ifosfamide-cisplatin (VeIP), for NSGCTs, 1697

Vincristine, for penile cancer, 1771

Viral hepatitis, STDs and, 1268–1271, 1269*t*

Virchow triad, in pregnancy, 283

Virtual reality trainers, for laparoscopic and robotic surgery, 232–233

Virtue Quadratic male sling, 2887

Virulent bacteria, 427–428

Virus-related tumors, of penis, 1742.e2–1742.e3, 1743*b*

- Bowenoid papulosis, 1742.e2
- HPV, 1742.e5
- Kaposi sarcoma, 1742.e5

Visceral injury

  - during laparoscopic and robotic surgery, 224
  - laparoscopic kidney surgery causing, 2307, 2307*f*

Visible hematuria, 247

Visual estimation targeting (VET), 3622

Visual obturator access, 464–465

Vital signs, 9

Vitamin D
  - in absorptive hypercalciuria, 2019
  - in calcium metabolism, 2015
  - in prostate cancer, 3463–3465
  - renal regulation of, 1914, 1914*f*

Vitamin D receptor (VDR), 2019
  - in prostate cancer, 3463–3465

Vitamin D_3-receptor analogues, to facilitate bladder filling and urine storage, 2713.e1

Vitamin E
  - for PD, 1611, 1616*t*
  - in prostate cancer prevention, 3476, 3476*f*

Vitiligo, 1305*f*, 1306

VLPP, Valsalva leak point pressure

Voided urine specimens, in urine collection, 1141

Voiding, Micturition
  - bashful bladder, 2628–2629
  - with normal bladder contraction, 2515–2516
  - therapy to facilitate, 2520*b*

Voiding cystourethrogram (VCUG), 39–40, 40*f*, 367, 389–390, 404–405, 406*f*, 414*f*, 415–416
  - bladder, 3011
  - of bladder diverticula, 2965*f*
  - for bladder/urethra, 415–416
    - cysts/masses, 415

        - infection, 415
        - obstruction of, 415, 416*f*
    - for differences of sex development, 416, 417*f*
    - fluoroscopy, 389
    - fundamentals of, 415
    - genitography, 390
    - of kidney/ureter, 415
        - cysts/masses, 415
        - infection, 415
        - obstruction of, 415
    - nuclear cystography, 389–390
    - of posterior urethral valves, 608, 609*f*
    - for scrotum/testes/internal genitalia, 416
    - trauma and, 415–416, 417*f*
    - for ureteral anomalies, 805
    - for vesicovaginal fistula, 2929, 2930*f*
- Voiding diaries, 476*f*
    - for PFDs evaluation, 2531
    - for urinary incontinence, in geriatric patients, 2920.e1–2920.e2
- Voiding dysfunction
    - after mid-urethral sling, 2871–2873, 2872*t*, 2873*b*
        - management of, 2871–2873
    - after pubovaginal sling procedure, 2845–2848, 2848*b*
        - surgical management of, 2846–2848, 2847*t*
    - behavioral treatment for, 2732
    - benign prostatic hyperplasia in, 3305, 3306*f*
    - classification of
        - functional, 2551
    - classification systems of, 2519–2524
        - Bors-Comarr, 2522–2523, 2523*b*
        - Bradley, 2524
        - functional, 2516*b*–2517*b*, 2518*t*, 2519*b*–2521*b*, 2520–2521
        - Hald-Bradley, 2523–2524, 2523*b*
        - International Continence Society, 2517, 2521*b*
        - Lapides, 2522–2523, 2522*b*
        - urodynamic, 2521–2522, 2522*b*
    - electrical stimulation in, 2746–2747, 2746*f*–2747*f*
    - HIV and, 1267

    - lower urinary tract dysfunction and, 2627
    - neurogenic, 2967
    - neuropathic
        - patterns of, 2600–2602
        - videourodynamics for, 2573*f*
    - postoperative, after retropubic suspension surgery, 2770
    - ureterocele and, 820
    - urodynamic studies of, functional classification, 2551
    - videourodynamics for, 2570

- von Brunn nests, of upper urinary tract, 2188
- von Hippel-Lindau disease (VHL), 759–761
    - classification of, 760, 760*t*
    - clinical features of, 760
    - etiology of, 760
    - evaluation of, 761
    - histopathology of, 760–761
    - screening for, 761, 761*t*
    - targeted molecular therapies for
        - basis of, 2332–2333, 2333*f*
        - combination and sequential therapy with, 2339–2341
        - mTOR pathway inhibitors, 2326–2327, 2338–2339, 2340*f*, 2340*t*
        - VEGFR-based, 2326–2327, 2333–2337, 2333*t*–2335*t*, 2336*f*, 2337*t*
    - treatment of, 761
- von Hippel-Lindau syndrome
    - genomic alterations in, 1354*t*, 1358, 2141–2143, 2143*t*, 2144*f*
    - RCC screening for, 2158
    - treatment of RCC in, 2173–2174, 2174*f*
- VOS repair, Vagino-obturator shelf (VOS) repair
- VTE, Venous thromboembolism
- VUDS, Videourodynamics
- Vulva, 1627.e1–1627.e2, 1627.e1*f*, 2436, 2436*f*–2437*f*
- Vulvar RMS, in pediatric patients, 1119
- VUR, Vesicoureteral reflux

VVB, Venovenous bypass

VVF, Vesicovaginal fistula

W

Wallace technique, in urinary diversion, 3187–3188, 3188*f*

Warburg effect, 96

WAS, Water avoidance stress

Watchful waiting, Surveillance
- for benign prostatic hyperplasia, studies on, 3329–3330, 3330*f*, 3330*t*
- for lower urinary tract symptoms, 3351
- for prostate cancer, 3541

Water
- filtrate transport, 1910–1911, 1911*f*, 1911*b*
- intake of, renal calculi and, 2009
- urothelium permeability to, 2467

Water avoidance stress (WAS), bladder pain syndrome and interstitial cystitis and, 2508

Water imbalance, diabetes insipidus, 2678

Water-filled catheters, for urodynamic studies, 2558

Watts factor (WF), 2658

Wavelength, 70*f*

WBS, Williams-Beuren syndrome

Webbed penis, 394, 878–879, 879*f*

Wedge resection, for large renal tumors, 2263, 2265*f*

Weight control, for prostate cancer, 3544

Weight loss, for OAB, 2647

Weight reduction, for urinary incontinence, 2734

Well differentiated liposarcomas, in retroperitoneum, 2229–2230

Wernicke encephalopathy, lower urinary tract dysfunction and, 2631

WHI, Women's Health Initiative

Whitaker test, 160
  for urinary tract obstruction, 780

White blood cell, priapism and, 1542

White coat hypertension, 352

White line of Toldt, 1866

Whole-body bone scan, 42

Williams-Beuren syndrome (WBS), lower urinary tract dysfunction and, 2631–2632

Wilms tumor, 402, 1096–1110, 1110*b*, 2181*t*, 2183
  biology and genetics of, 1096–1099, 1097*t*, 1354*t*
  epidemiology of, 1096
  pathology of, 1099–1101
    after preoperative chemotherapy, 1100
    anaplasia, 1100
    favorable histology, 1100, 1100*f*
    nephrogenic rests, 1100–1101, 1101*f*
  preoperative evaluation of, 1101–1103, 1103*t*
  screening for, 1098–1099, 1099*f*, 1099*t*
  treatment of
    chemotherapy, 1106–1108, 1107*f*
    late effects of, 1108–1110
    partial nephrectomy, 1107–1108
    surgical considerations of, 1103–1104, 1105*f*

Window technique, 1845

Wisconsin Stone Quality of Life (WiSQoL) questionnaire, 175

Wnt signaling pathway, 3276

WNT4 gene, 992*f*, 992*t*, 993

Wolffian duct (WD), 324*f*, 334–335, 714

Women's Health Initiative (WHI), 2710

Wong-Baker FACES, 448*f*

World Health Organization, RCC classification system of, 2148*t*

Wound, Surgical wounds

  genital bite, 1293, 1294*f*

Wound dressing, 151

Wound healing, and PD, 1603–1604

Wound infections, Surgical site infections

  after laparoscopic and robotic surgery, 231

W-stapled reservoir, for cutaneous continent urinary diversion, 3228–3229, 3231*f*

WT1 gene, 991–992, 992*f*, 992*t*, 1097, 1097*t*

WTX gene, 1097–1098, 1097*t*

X

Xanthine stones

  in renal calculi, 2031–2032

  surgical management of, 2077.e3

Xanthogranulomatous pyelonephritis (XGP), 444, 1177–1179, 1178*f*–1179*f*

Xenograft, for pubovaginal sling, 2835

  outcomes of, 2843–2844, 2844*t*

XGP, Xanthogranulomatous pyelonephritis

Y

Y chromosome microdeletion testing, for male infertility, 1442–1443

Yang-Monti technique, 709, 710*f*

Yeast, in urine, 22*f*, 23

Yellowfins stirrups, 3580

Yerba mate, UTUC risk and, 2186

Yoga, for female orgasmic disorder, 1647

Yolk sac, 318*f*

Yolk sac tumors (YSTs)

- in female pediatric patients, 1120
- testicular
  - histology of, 1683*f*, 1684
  - in pediatric patients, 1123–1124, 1124*f*

Young-Dees-Leadbetter bladder neck reconstruction, 685–686

- modified, 555*f*–556*f*
- results with, 685–686
- technique for, 685

YSTs, Yolk sac tumors

Z

Zanoterone, for benign prostatic hyperplasia, 3376

Zika virus, STD and, 1264–1268

Zinc, in prostatic secretions, 3296–3297

Zinc α_2-glycoprotein, in prostatic secretions, 3302–3303

Zipper injuries, to penis, 3051

Zoledronate, 3703

Zona fasciculata, in adrenal cortex physiology, 2357, 2357*f*, 2358*t*

Zona glomerulosa, in adrenal cortex physiology, 2356–2357

Zona reticularis, in adrenal cortex physiology, 2357

Zonal anatomy, prostate, 1379*f*–1380*f*, 1380–1381

Zonisamide, in stone formation, 2033
